C++

By: Jayant

Why Choose This book?

- Good Quality Content
- Easy to Understand
- Images and colors are used for increase performance
- highlight important points for students

Index

Description	Page. No
What is C++	5
Features of C++	5
Why should choose only C++	5
D/B C or C++	6
Why use (using namespace std)	7
Setup C++ in VS Code	8-18
What is Console	19
Tokens	19
Basic Structure of C++	20
Types of Errors	21-26
Variables	27-28
Input/Output Function	29-30
Comments	31-32
Keywords	33-34
Identifiers	35-36
Constants	37-38
Datatypes	39-41
Header Files and its types	42-49
Functions and its types	50-57
Recursion	58-64
Special Symbols	65

Operators	66-78
Strings	79-86
Conditional Statement (if/else or switch)	87-95
Loops	96-102
Jumping Statements	103-106
Pointers	107-108
Structure	109-111
Union	112-113
Storage Classes	114-119
Arrays and its types	120-126
Type Casting	127-128
Size-of operator	129
Pre-Processor Directives	130-132
OOPs(Object Oriented Programming)	
Classes and Objects	133-134
Encapsulation	135-136
Abstraction	137-138
Constructor	139-145
Inheritance	146-157
Scope resolution operator	158-159
Access Specifiers	160-164
Polymorphism	165-170
This pointer	171-172
Dynamic Memory Allocation	173-175

File Handling	176-181
Exception Handling	182-183
Friend Function	184-185

What is C++

- (i)C++ is developed by Bjarne Stroustrup in 1979 at AT & Bell laboratory in California America.
- (ii)C++ is an object-oriented programming language or it's a high-level language.
- (iii)It is used for developing operating systems, games or etc.
- (iv)It is basically advance version of C language because C doesn't support OOPs concept but C++ is supported OOPs concept.
- (v)C++ is best language for doing DSA (Data Structure and algorithms).

Features of C++

- (i)Simple to use: C++ gives easy syntax to developers for better understanding of code and easy to write.
- (ii)OOPs: C++ support object-oriented programming because it gives security to protect our data.
- (iii)High Level Language: C++ is a high-level language because developers easily write source code in C++ or understand it, then after C++ converted source code to machine code.
- (iv)Compiler based: C++ follows by compilation process; it means compiler check whole source code; if source code is completely correct then give output otherwise give error according to mistake in source code.

Why should choose only C++?

- (i)There are various programming languages or different type of languages are present in market but C++ has given high speed and performance.
- (ii)It is directly access to hardware.

Difference between C and C++

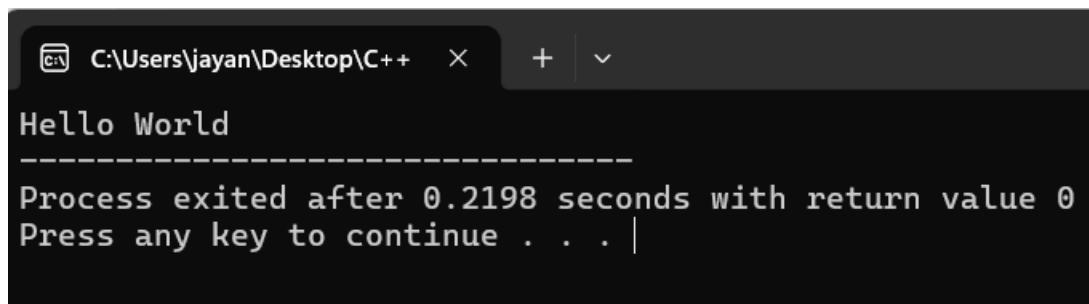

C	C++
1.C is a procedural language.	1.C++ is an Object-oriented programming language.
2.Dennis Ritchie was developed by C language in 1972	2.While C++ was developed by Bjarne Stroustrup in 1979.
3.C doesn't support OOP's concept	3.C++ support OOP's concept
4.C support main function as void function	4.But C++ doesn't support void ad main function
5.In C language, use format specifier.	5.In C++, cannot use format specifier.
6.C doesn't support access specifier.	6.C++ support access specifier for data security.
7.C is less secure programming language as compared to C++.	7.C++ more secure programming language as compared to C.
8.C is nearest to hardware.	8.C++ also nearest to hardware.
9.<stdio.h> is used for basic input/output functions.	9.<iostream> is used for basic input output functions.
10.C doesn't support using namespace std.	10.C++ support using namespace std.
11.For memory allocation and deallocation use malloc, calloc, re-alloc or free.	11.For memory allocation and deallocation use new and delete operators
12.No supported Exception Handling	12.Supported Exception Handling.
13.(.C) extension is used for creating a C file.	13.(.cpp) extension is used for creating C++ file.
14.DevC++ is best ide for C language.	14.DevC++ is also best ide for C++ language.
15.Applications: Creating Operating systems, developing new languages, etc.	15.Game Development, GUI support, Compilers, etc.

Why use (using namespace std)

- (i) In C++, using namespace std is a directive that brings all the identifiers from the std namespace into the current scope.
- (ii) This means you can use standard library functions, classes, and objects like cout, cin, and strings without having to prefix them with std::.

```
9
10 #include<iostream>
11 using namespace std; |
12 main(){
13 cout<<"Hello World";
14 }
15
```

Output:

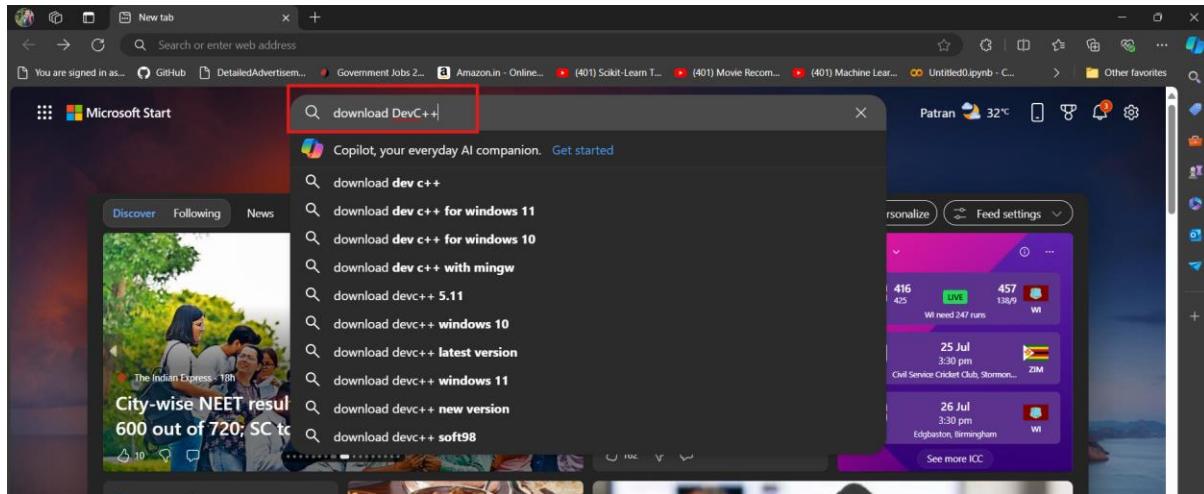

A screenshot of a terminal window titled 'C:\Users\jayan\Desktop\C++'. The window displays the following text:
Hello World

Process exited after 0.2198 seconds with return value 0
Press any key to continue . . . |

Setup C++ in VS Code

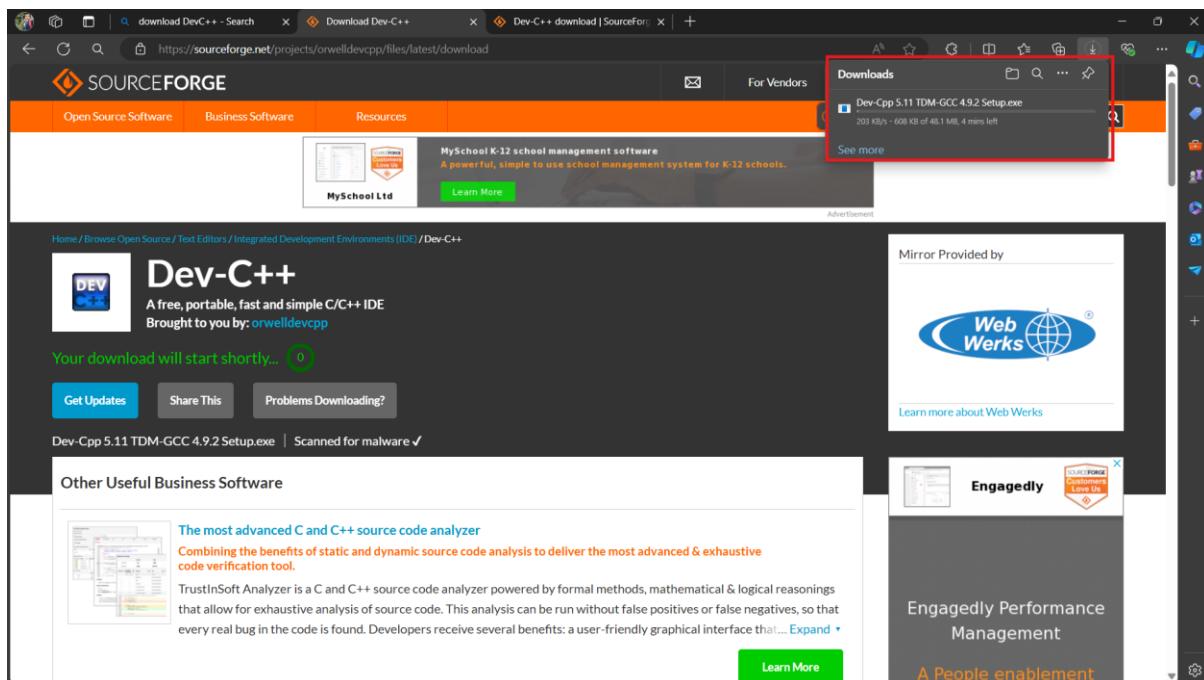

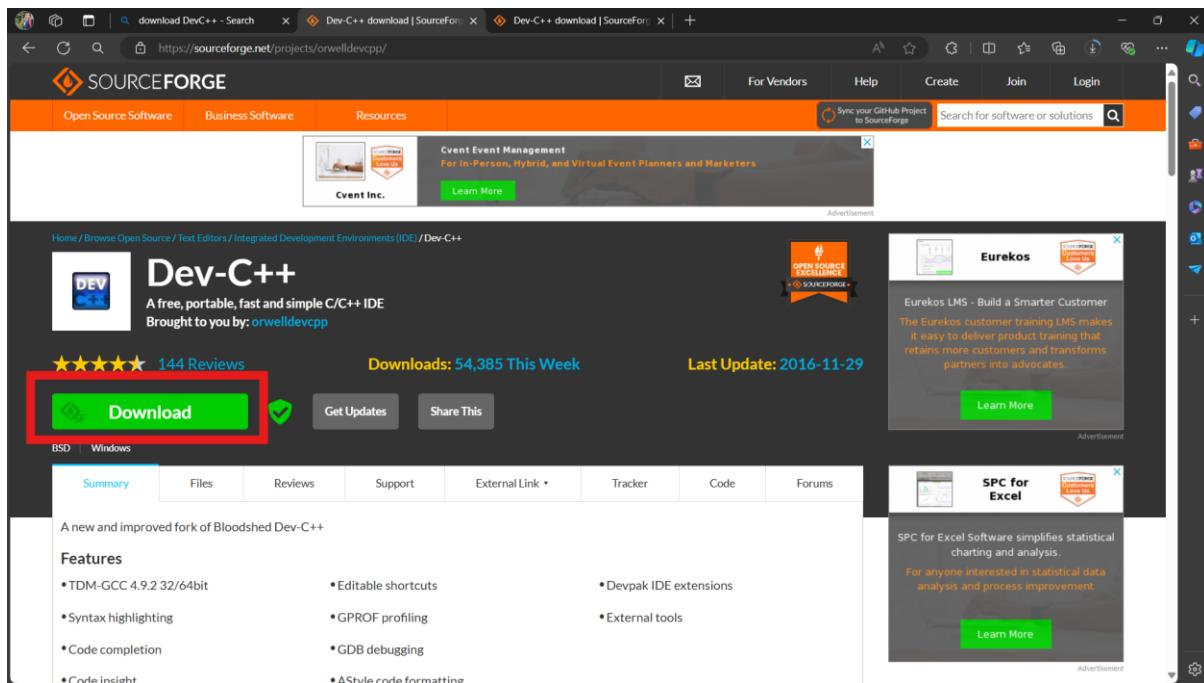

Step1: Open any browser or search download DevC++.

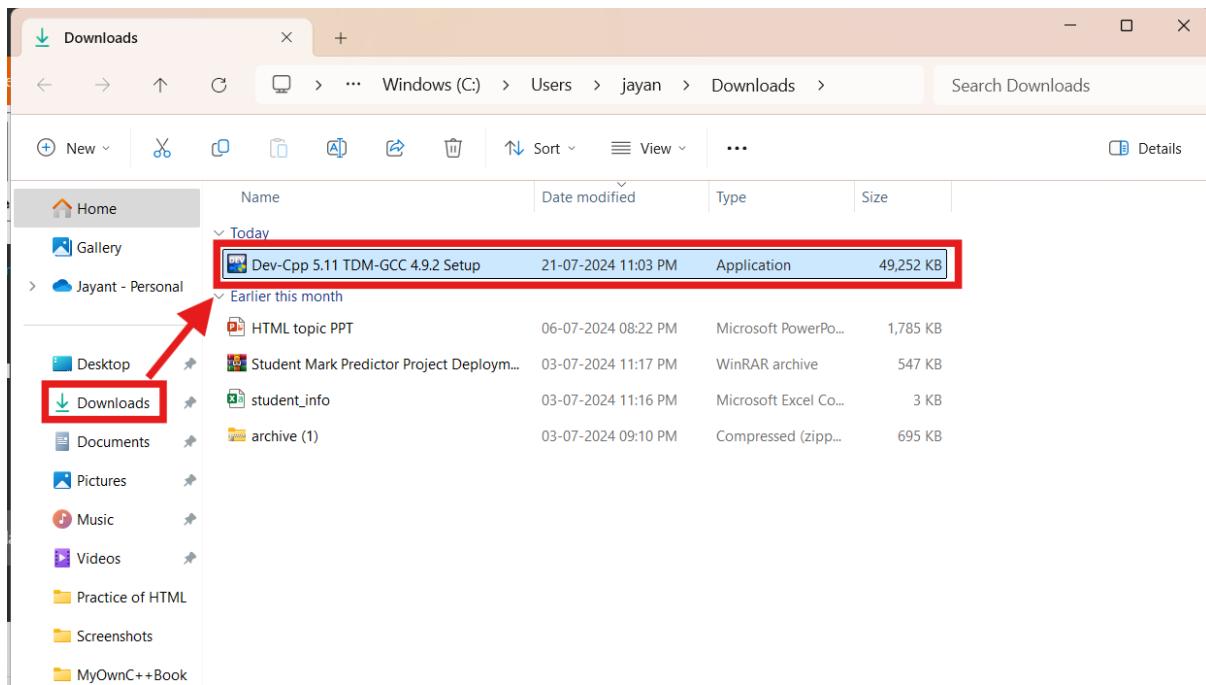

Step2: Click on Source Forge Website.

A screenshot of a Microsoft Bing search results page. The search term "download DevC++" is entered in the search bar. The results page shows various links, including one for "Dev-C++" which is highlighted with a red box. This link leads to the SourceForge.net website. The SourceForge page for Dev-C++ includes sections for "Download", "Portable Releases", and "Setup Releases".

Step3: Click Download Button.

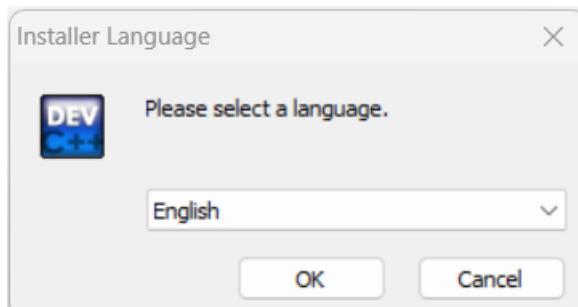

Step4: After Download, go to folder where you have downloaded DevC++ setup file or download file, then double click it.

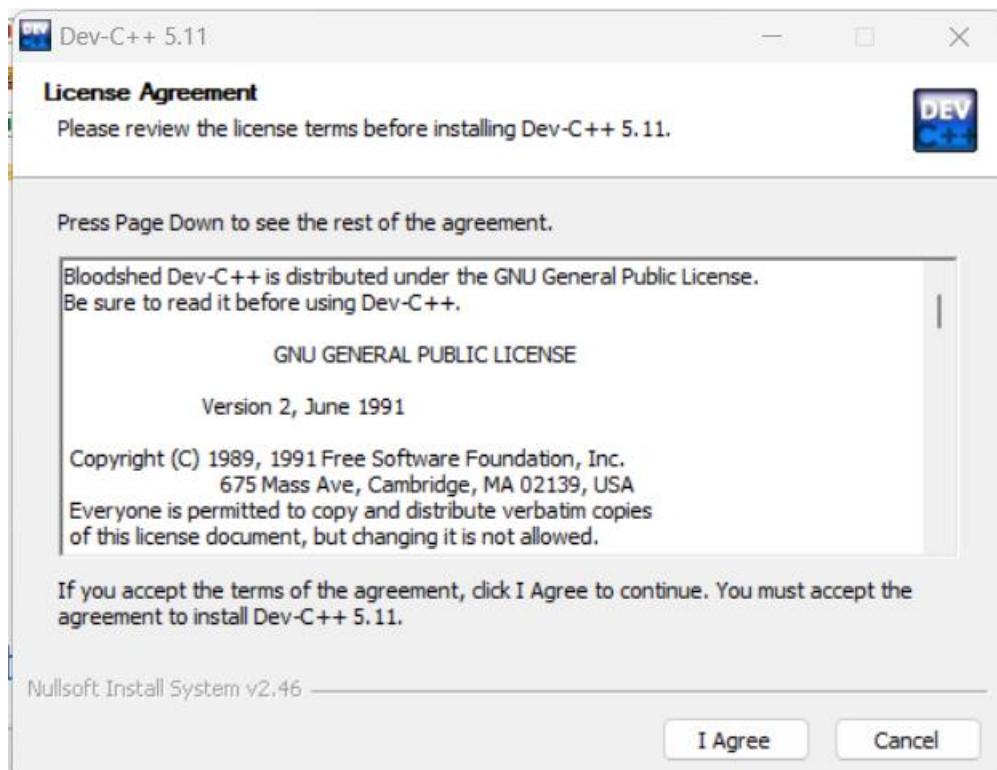

Step5: After double click, installation process will be start

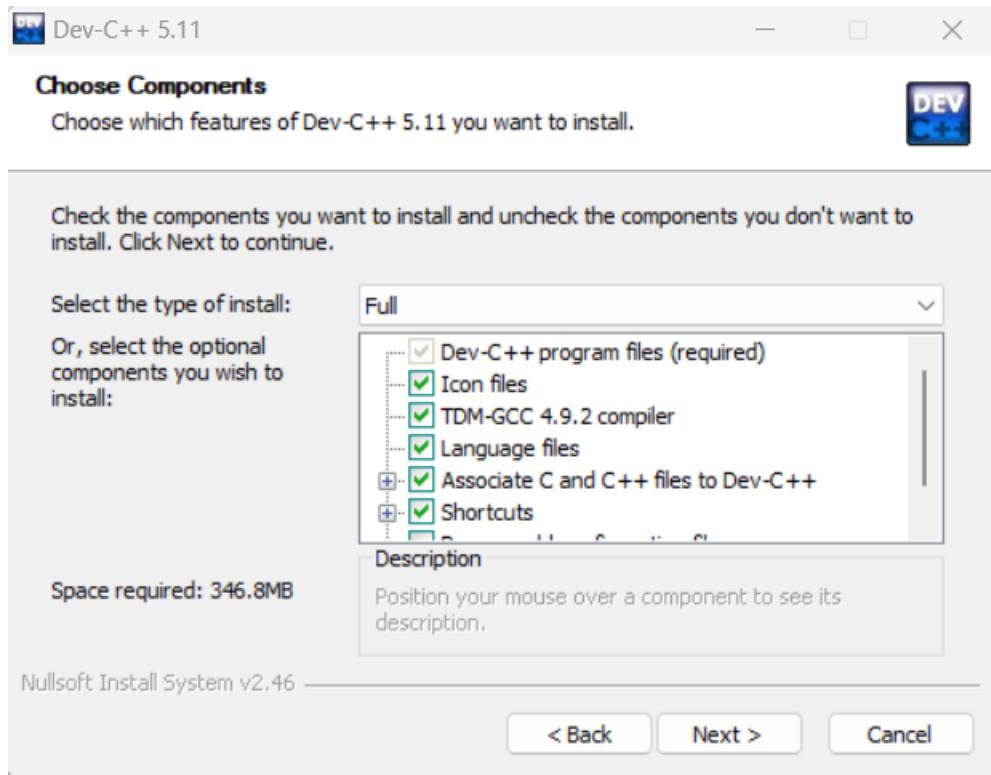

Step6: Select language, then click ok (By default selected english)

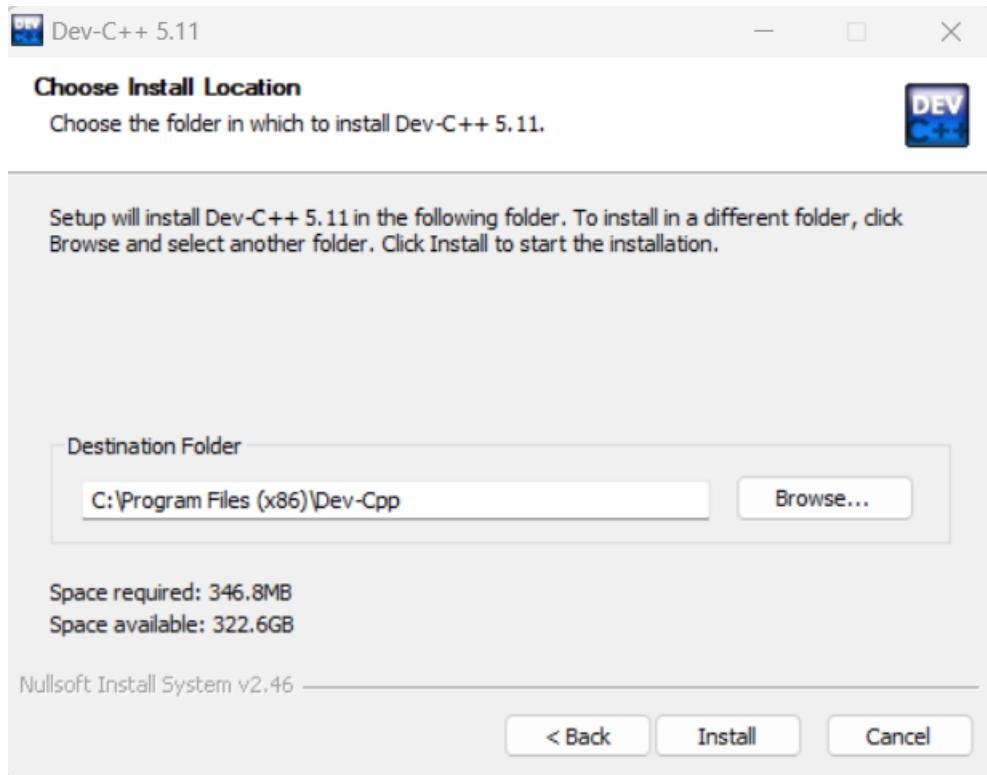

Step7: Read Agreement and click I Agree

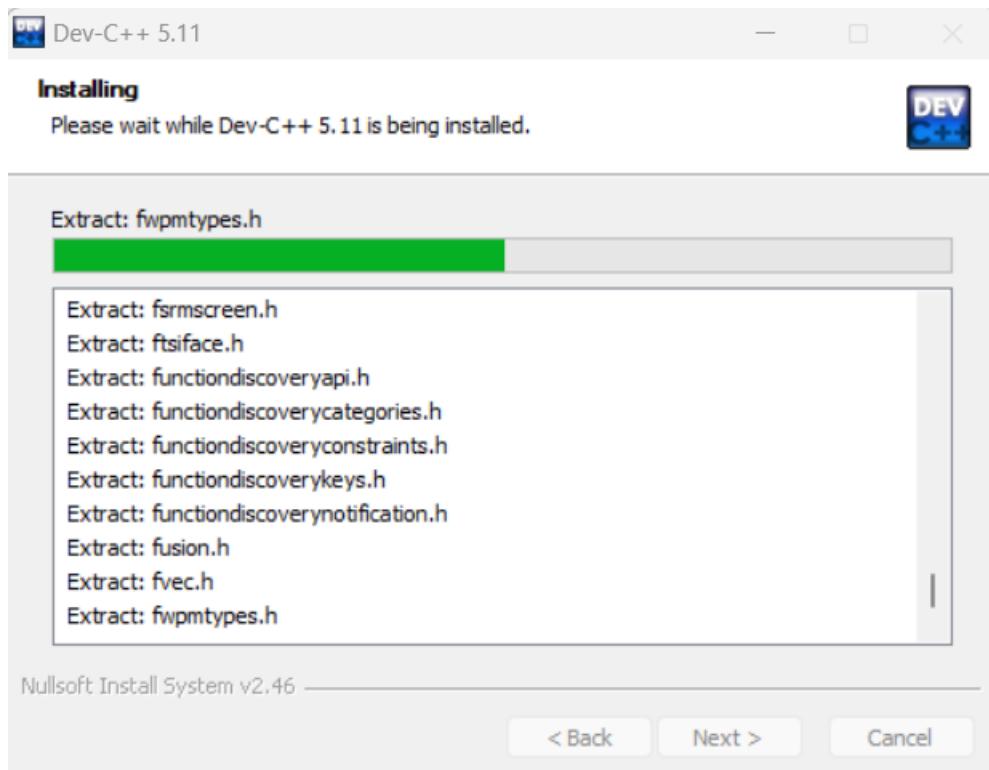

Step8: Choose Components; No need to change; Simply click on next

Step9: Select location where you want to store files of DevC++; if you want to use by default location, then click to install button

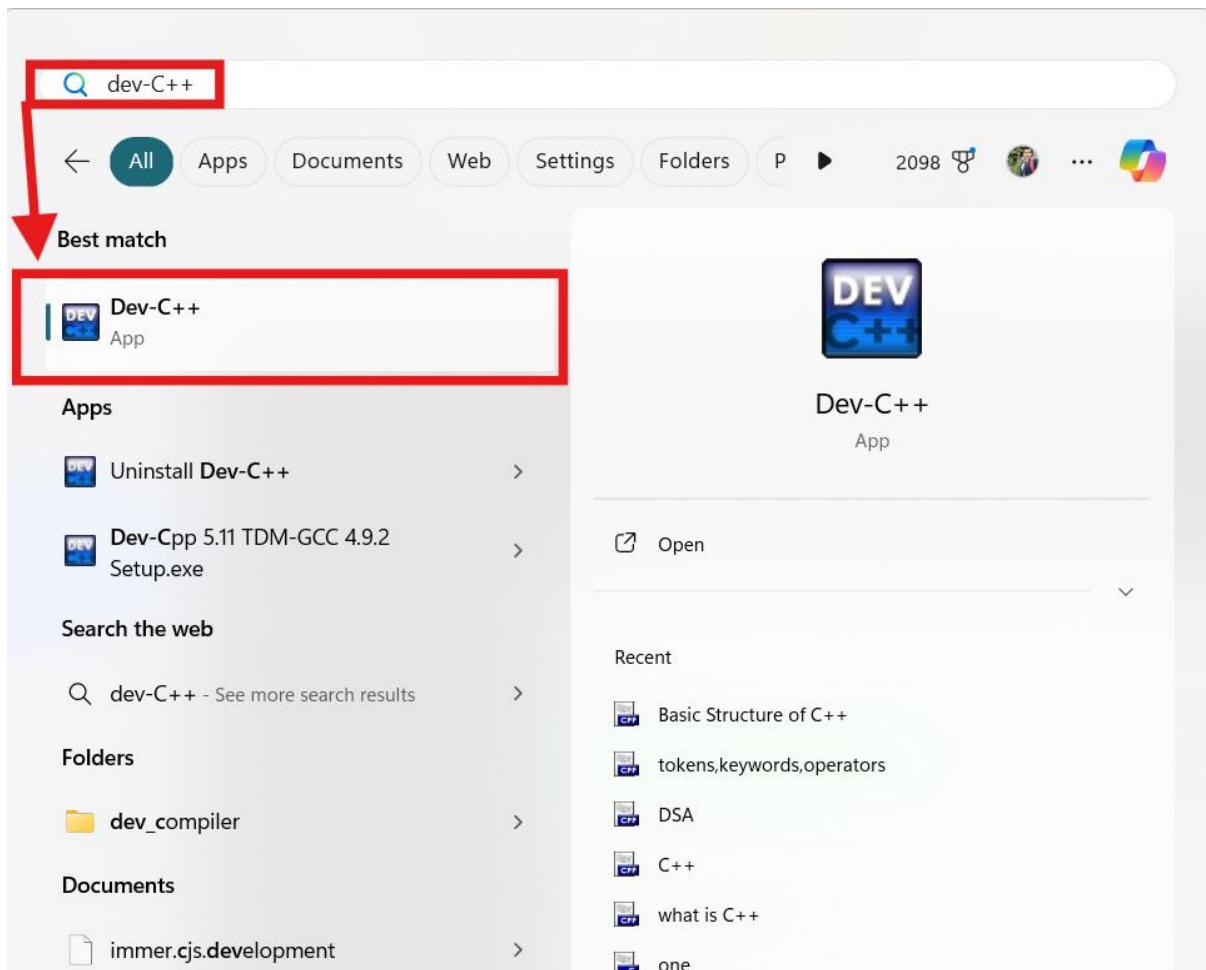

Step10: Wait until installation complete

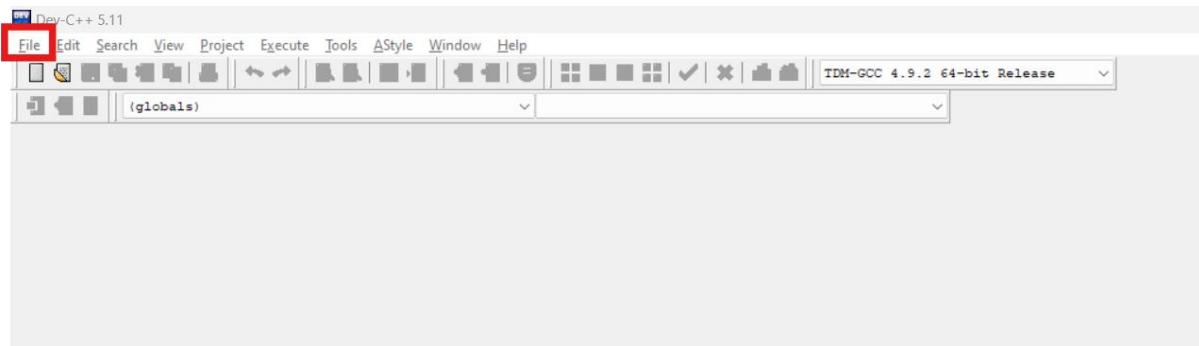

Step11: If you want to run DevC++ automatically at first time, then click on checkbox, then [click finish button](#) after installation process

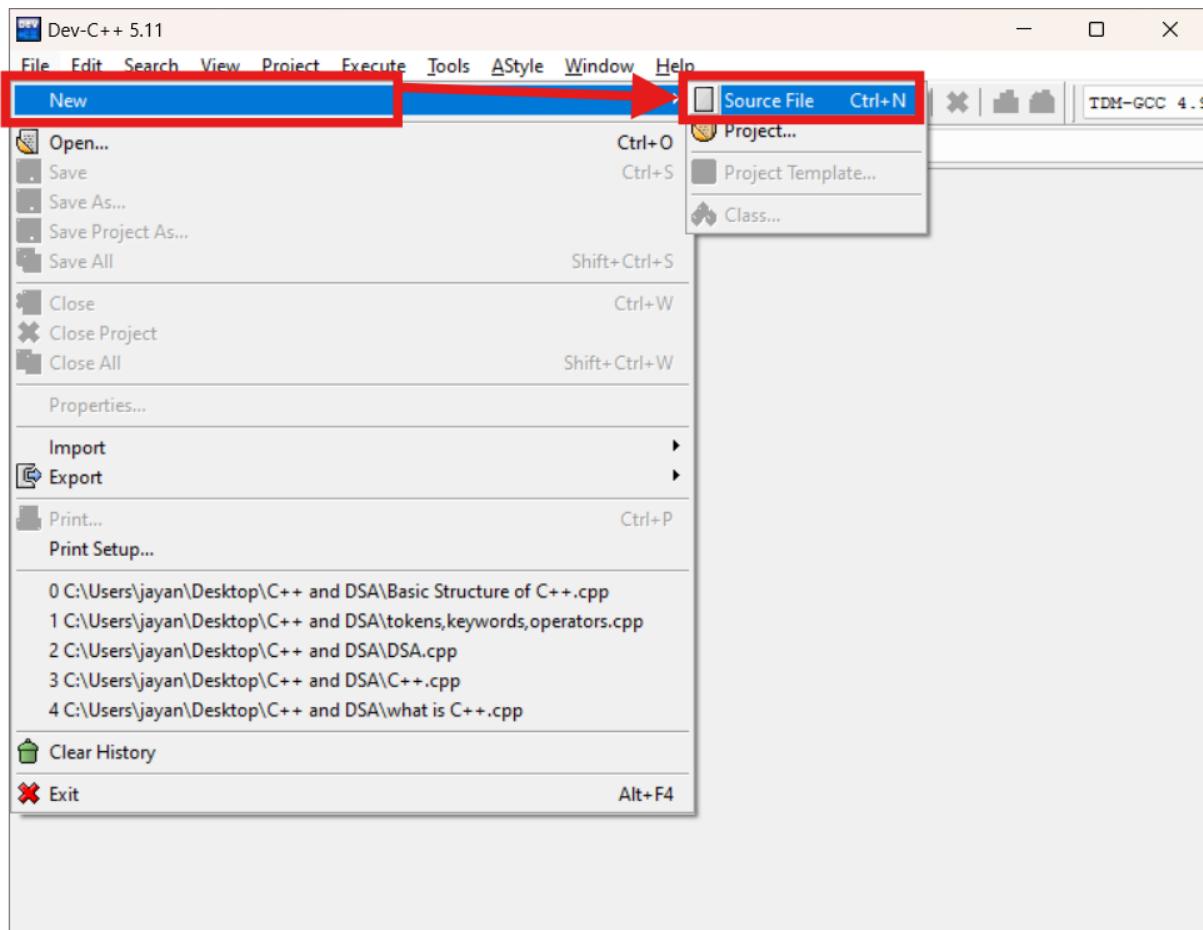

Step12: Search in windows devC++ and click it

Step13: After opening DevC++, click on file tab

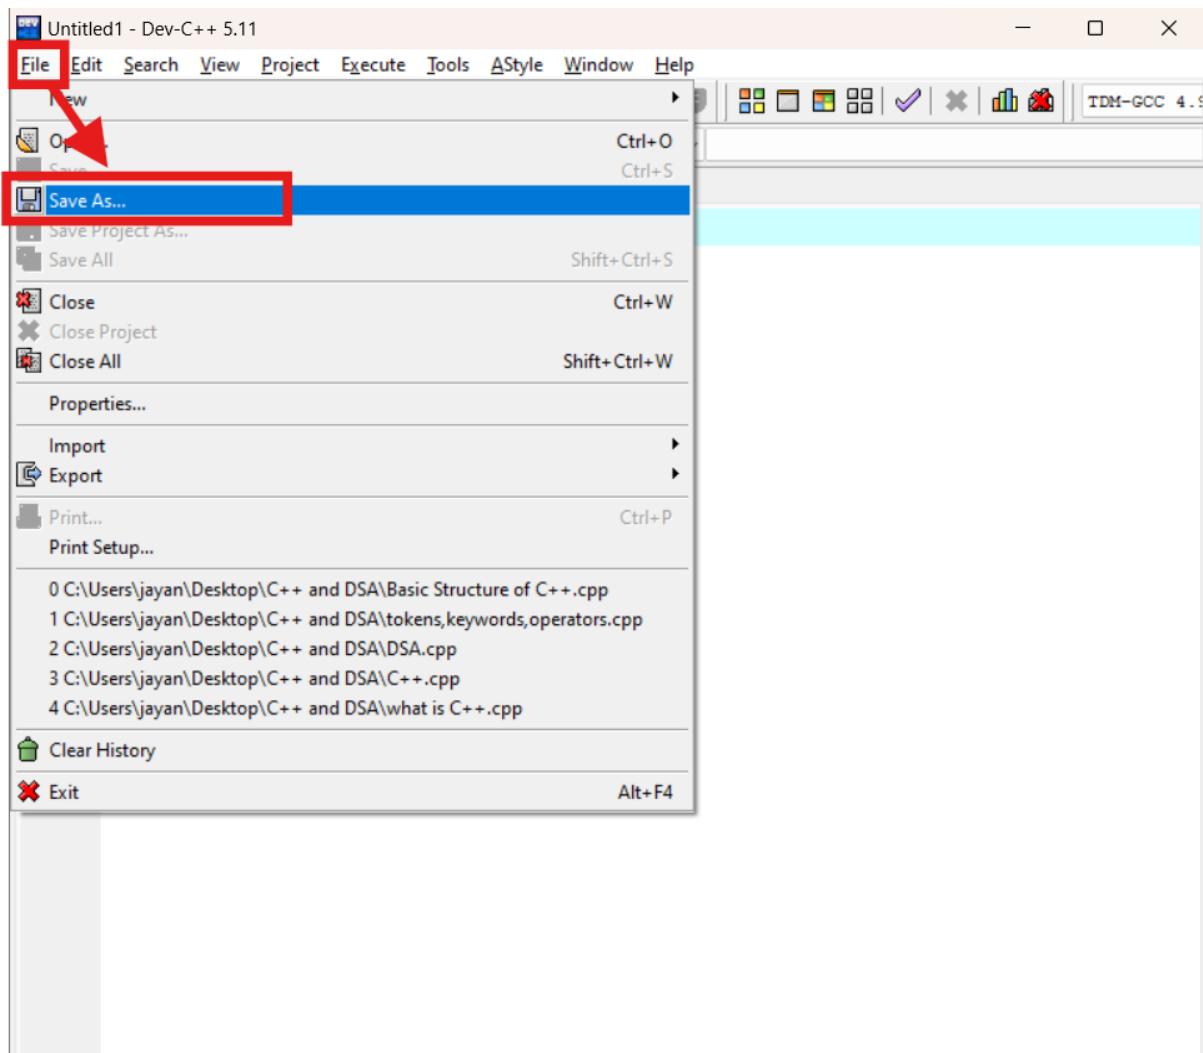

Step14: In file tab, click new option then click source file

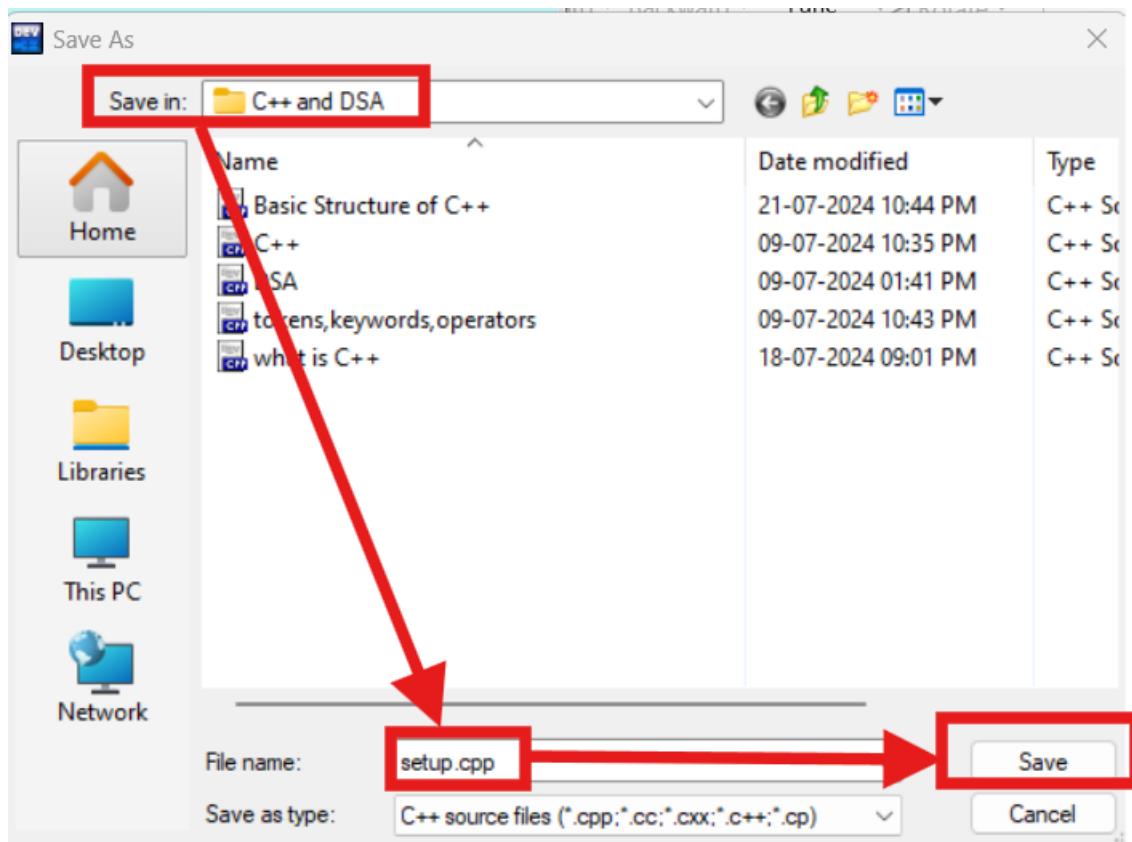

Step15: After click source file option, new file will be generated

Step16: Again go to file tab and click **SaveAs** option for first time save the file

Step17: Select location where you want to save the file and give file name(anyname)with (.cpp) extension and click save.

Step18: Lastly Write Source code in file and click compile and run button (file will be run).

The screenshot shows the Dev-C++ IDE interface. At the top, the title bar displays "C:\Users\jayan\Desktop\C++ and DSA\setup.cpp - Dev-C++ 5.11". The menu bar includes File, Edit, Search, View, Project, Execute, Tools, AStyle, Window, and Help. The toolbar contains various icons for file operations like Open, Save, and Print. The status bar at the bottom right shows "TDM-GCC 4.9".

The main area shows a code editor with a red box highlighting the entire content of the file "setup.cpp". The code is:

```
1 #include<iostream>
2 using namespace std;
3 int main(){
4     cout<<"Setup Checking";
5 }
```

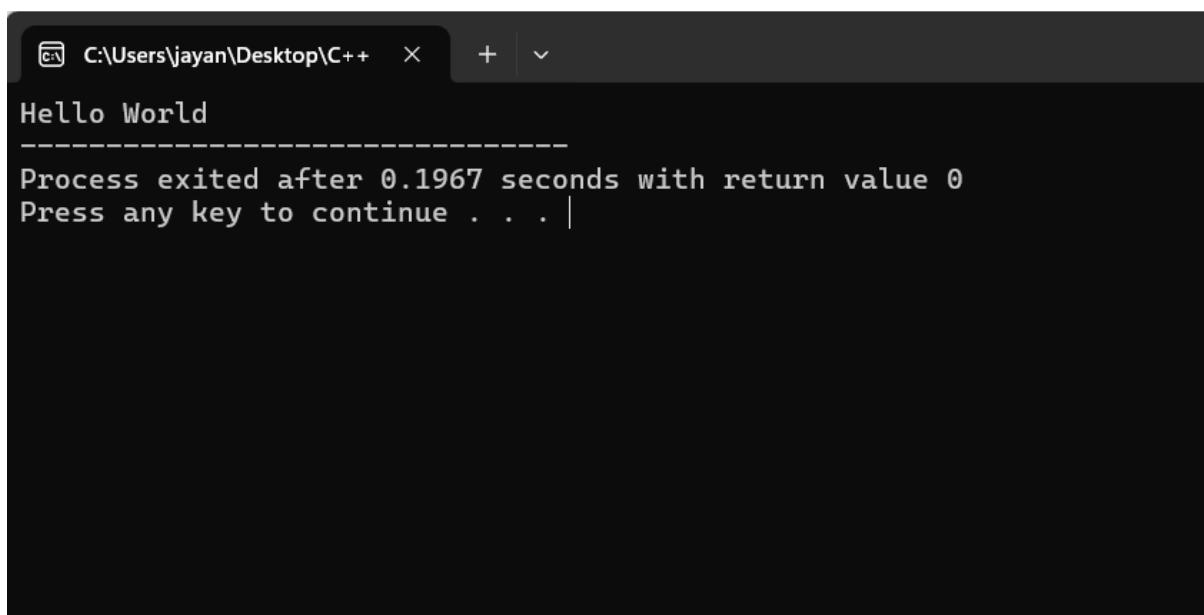

A red arrow points from the top red box down to the "Compile Log" tab in the bottom window. The "Compile Log" tab is selected and shows the following compilation results:

- Errors: 0
- Warnings: 0
- Output File: C:\Users\jayan\Desktop\C++ and DSA\setup.exe
- Output Size: 1.83193492889404 MiB
- Compilation Time: 1.67s

What is Console

- (i)Console is an output window shown at runtime.
- (ii)User cannot change result of the console window.

.

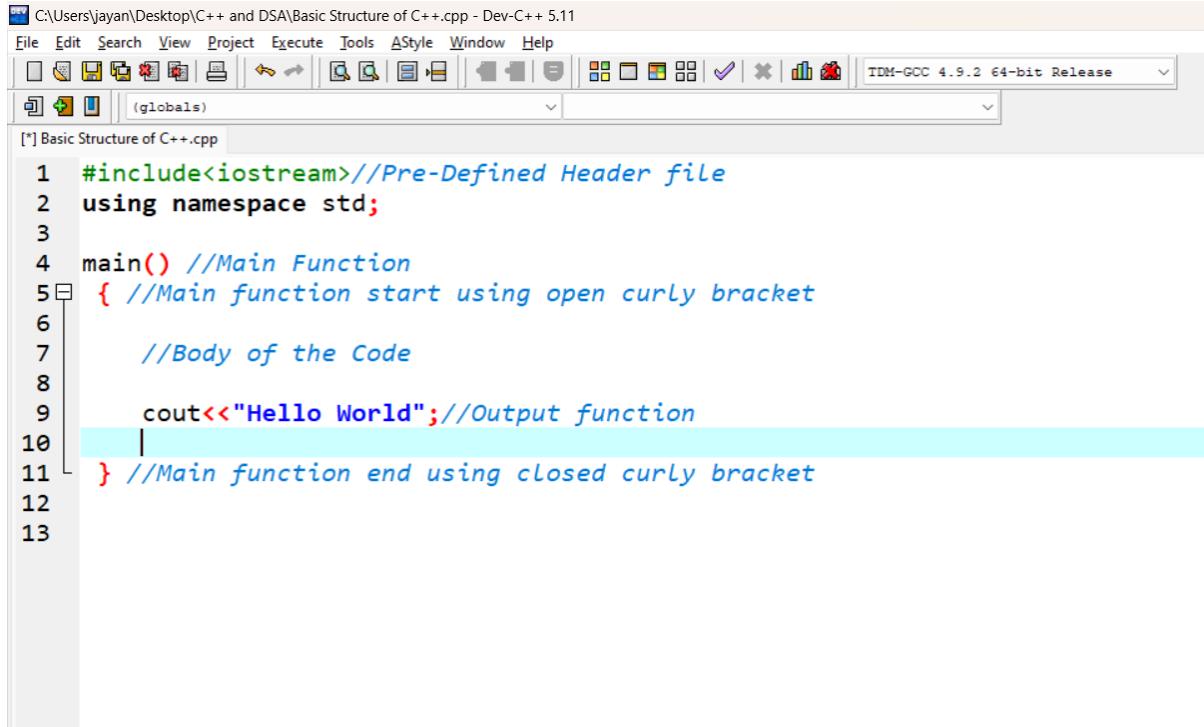

A screenshot of a terminal window titled "C:\Users\jayan\Desktop\C++". The window displays the following text:
Hello World

Process exited after 0.1967 seconds with return value 0
Press any key to continue . . . |

Tokens

Every Individual smallest unit is called Tokens like: keyword, identifier, literal, operator, or symbol etc.

Basic Structure of C++

The screenshot shows the Dev-C++ IDE interface. The title bar reads "C:\Users\jayan\Desktop\C++ and DSA\Basic Structure of C++.cpp - Dev-C++ 5.11". The menu bar includes File, Edit, Search, View, Project, Execute, Tools, AStyle, Window, and Help. The toolbar contains various icons for file operations like Open, Save, Print, and Build. The status bar at the bottom right says "TDM-GCC 4.9.2 64-bit Release". The code editor window displays the following C++ code:

```
1 #include<iostream> //Pre-Defined Header file
2 using namespace std;
3
4 main() //Main Function
5 { //Main function start using open curly bracket
6
7     //Body of the Code
8
9     cout<<"Hello World"; //Output function
10    |
11 } //Main function end using closed curly bracket
12
13
```

Basic structure is compulsory code should write in C++ file because it is just like a protocol (rules and regulations) have necessary to write.

Steps:

Step1: `#include<iostream>` It is a pre-defined header file. It's contain basic input or output functions.

Step2: `using namespace std` `using namespace std` is a directive that brings all the identifiers from the std namespace into the current scope.

Step3: `main()` This is the main function, it's responsible for execution of source code.

Step4: { The open curly bracket is used for start the block of code.

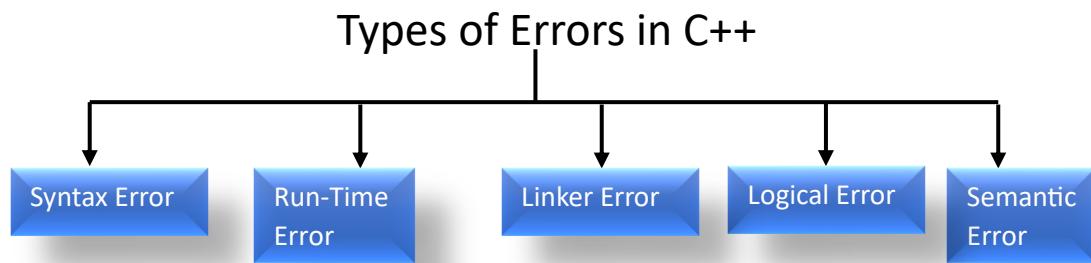

Step5: Write body or logic of the C++.

Step6: } The close curly bracket is used for end of the code block.

Errors in C++

(i) Errors are the problems or the fault that occur in the program, which makes the behavior of the program abnormal, and experienced developers can also make these faults.

(ii) Programming errors are also known as the bugs or faults, and the process of removing these bugs is known as debugging.

Syntax Error: (i) Syntax error are also known as the compilation errors as they occurred at the compilation time, or we can say that the syntax errors are thrown by the compilers.

(ii) These errors are mainly occurred due to the mistakes while typing or do not follow the syntax of the specified programming language.

(iii) These mistakes are generally made by beginners because they are new to the language. These errors can be easily debugged or corrected.

(iv) Example: (; { “ ...)

The screenshot shows the Dev-C++ IDE interface. The main window displays a C++ source code file named "Basic Structure of C++.cpp". The code contains a simple "Hello World" program:

```
1 #include<iostream>
2 using namespace std;
3 int main(){
4     cout<<"Hello World"
5 }
6
7 }
```

A red box highlights the line "cout<<"Hello World"" and a red arrow points from this box to a message window titled "Message". The message window shows the following error:

Line: 6 Col: 5 File: C:\Users\jayan\Desktop\C++ and DSA\Basic Structure of C++.cpp
in function 'int main()':
Error] expected ';' before ']' token

Run-Time Error:(i) Sometimes the errors exist during the execution-time even after the successful compilation known as run-time errors.

(ii)When the programming is running, and it is not able to perform the operation is the main cause of the run-time error.

(iii)The division by zero is the common example of the run-time error. This error is very difficult to find, as the compiler does not point to these errors.

(iv)Sometimes run-time error gives simplest warning but source code will be executed and it gives undesired-output.

The screenshot shows the Dev-C++ integrated development environment. The main window displays a C++ source code file named "Basic Structure of C++.cpp". The code contains a main function that declares an integer variable 'a' and initializes it to 10. It then attempts to calculate the total by dividing 'a' by 0, which is highlighted with a red box. The code also outputs the result to the console using cout. The bottom part of the interface is a compiler log window titled "Compiler (2)" which shows a warning about division by zero at line 5, column 13.

```
1 #include<iostream>
2 using namespace std;
3 main(){
4     int a=10;
5     int total=a/0;
6     cout<<"Total is:"<<total;
7
8 }
9
10
```

Compiler (2) Resources Compile Log Debug Find Results Close

Line Col File Message

C:\Users\jayan\Desktop\C++ and DSA\Basic Structure... In function 'int main()':

5 13 C:\Users\jayan\Desktop\C++ and DSA\Basic Structure of... [Warning] division by zero [-Wdiv-by-zero]

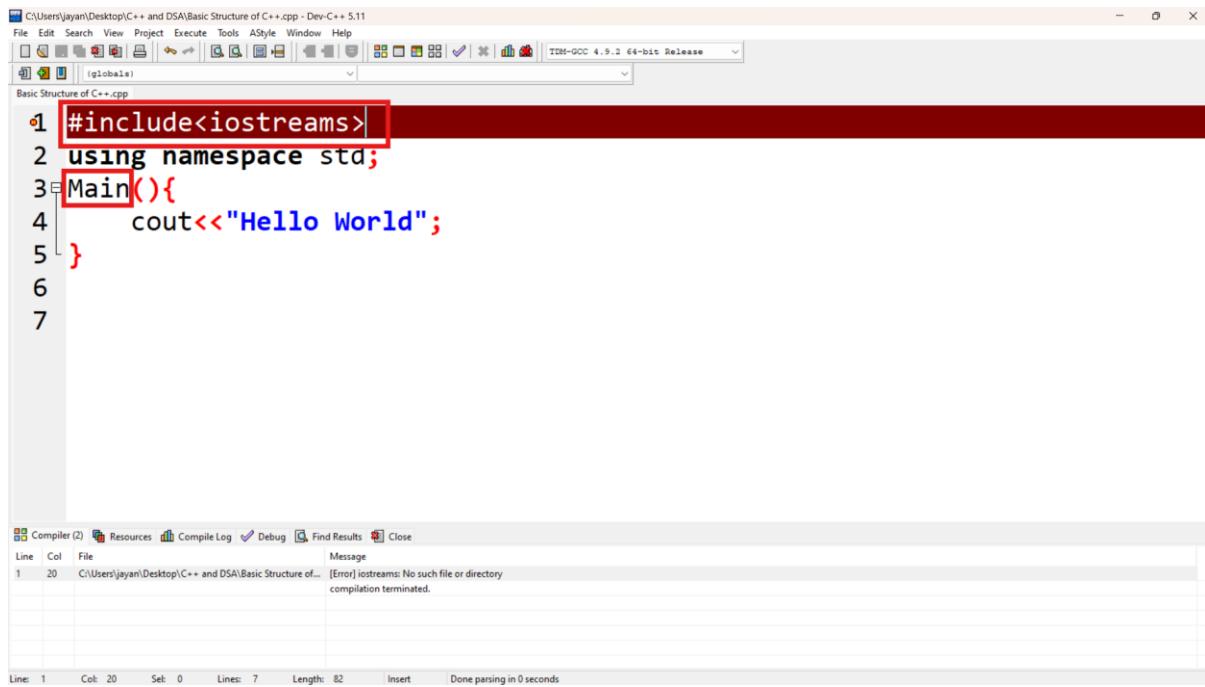

Output:

The screenshot shows a terminal window with a dark background and white text. The window title is "C:\Users\jayan\Desktop\C++". The output of the program is displayed, showing that the process exited after 1.907 seconds with a return value of 3221225620. A message at the end of the output asks the user to press any key to continue.

```
Process exited after 1.907 seconds with return value 3221225620
Press any key to continue . . . |
```

Note: Any number divided by 0 are gives not defined result in mathematics.

Linker Error: Linker errors are mainly generated when the executable file of the program is not created. This can be happened either due to the wrong function prototyping or usage of the wrong header file.

The screenshot shows the Dev-C++ IDE interface. The code editor window displays a C++ file named "Basic Structure of C++.cpp". The code contains the following lines:

```
1 #include<iostreams>
2 using namespace std;
3 Main(){
4     cout<<"Hello World";
5 }
6
7
```

The first two lines are highlighted with a red box. The third line, "Main()", is also highlighted with a red box. The status bar at the bottom shows the message "Done parsing in 0 seconds". Below the code editor is the compiler output window, which shows the following message:

```
Line: 1 Col: 20 Sel: 0 Lines: 7 Length: 82 Insert Done parsing in 0 seconds
Message
1 20 C:\Users\jayan\Desktop\C++ and DSA\Basic Structure of... [Error] iostreams: No such file or directory
compilation terminated.
```

Logical Error: (i) The logical error is an error that leads to an undesired output. These errors produce the incorrect output, but they are error-free, known as logical errors.

(iii) These types of mistakes are mainly done by beginners. The occurrence of these errors mainly depends upon the logical thinking of the developers.

The screenshot shows the Dev-C++ IDE interface. The code editor window displays the following C++ code:

```
1 #include<iostream>
2 using namespace std;
3 main(){
4     for(int i=0;i<=3;i++){
5         if(i==4){
6             cout<<i;
7             continue;
8         }
9     }
10}
11
12
13
```

A red rectangular box highlights the code block from line 5 to line 8. The compiler log window below shows the compilation results:

```
Compilation results...
-----
- Errors: 0
- Warnings: 0
- Output Filename: C:\Users\jayan\Desktop\C++ and DSA\Basic Structure of C++.exe
- Output Size: 1.8319263458252 MiB
- Compilation Time: 0.31s
```

At the bottom, status bar information includes: Line: 8, Col: 10, Sel: 0, Lines: 25, Length: 323, Insert, Done parsing in 0.016 seconds.

Output:

The terminal window displays the following output:

```
Process exited after 1.489 seconds with return value 0
Press any key to continue . . . |
```

Semantic: Semantic error are the errors that occurred when the statements are not understandable by the compiler.

The screenshot shows the Dev-C++ IDE interface. The code editor window displays the following C++ code:

```
1 #include<iostream>
2 using namespace std;
3 main(){
4     string name="Hello";
5     int name_letter=name;
6     cout<<"Number of letters are in this String:"<<name_letter;
7 }
8
9
```

A red box highlights the line `int name_letter=name;`. The message window at the bottom shows the error:

In function 'int main()':
[Error] cannot convert 'std::string (aka std::basic_string<char>)' to 'int' in initialization

Variables

(i) Variable is a name given to a memory location where we can store different values of the same datatype during the program execution.

(ii) In other words, a variable can be defined as a storage container to hold values of the same datatype during the program execution.

(iii) A variable name may contain letters, digits or underscore

Rules to specify a variable name:

(i) Variable name should not start with a digit.

(ii) Keywords should not be used as variable name.

(iii) A variable name should not contain any special symbol except underscore

(_).

The screenshot shows the Dev-C++ IDE interface. The main window displays a C++ source code file named "Basic Structure of C++.cpp". The code includes standard headers, namespaces, and a main function that adds two integers and prints the result. The code editor highlights certain parts of the code in red, specifically the variable declarations and the assignment operator. Below the code editor is a status bar showing the current compiler settings: "TDM-GCC 4.9.2 64-bit Release". The bottom part of the interface shows the "Compiler" tab of the toolbars, and the "Compile Log" tab is active, displaying the compilation results which show no errors or warnings.

```
1 #include<iostream>
2 using namespace std;
3 main(){
4     int num1=10;
5     int num2=20;
6     int sum=num1+num2;
7     cout<<"Addition of Two Numbers is:"<<sum;
8 }
9
```

Compilation results...

- Errors: 0
- Warnings: 0
- Output Filename: C:\Users\jayan\Desktop\C++ and DSA\Basic Structure of C++.exe
- Output Size: 1.83244895935059 MiB
- Compilation Time: 0.33s

Output:

```
C:\Users\jayan\Desktop\C++ + 
Addition of Two Numbers is:30
-----
Process exited after 1.646 seconds with return value 0
Press any key to continue . . . |
```

Input/Output Function

Every C++ program perform two main functions: accept data as input, process data and produces output.

(i) Input function refers to accepting of data while output function refers to the presentation of data.

(ii) Normally input is accepted keyboard and output is displayed to screen.

(iii) C++ has two input output function: 1. cin 2. cout

Cin: cin is used for taking input from user while

Cout: cout is used for display output on console window.

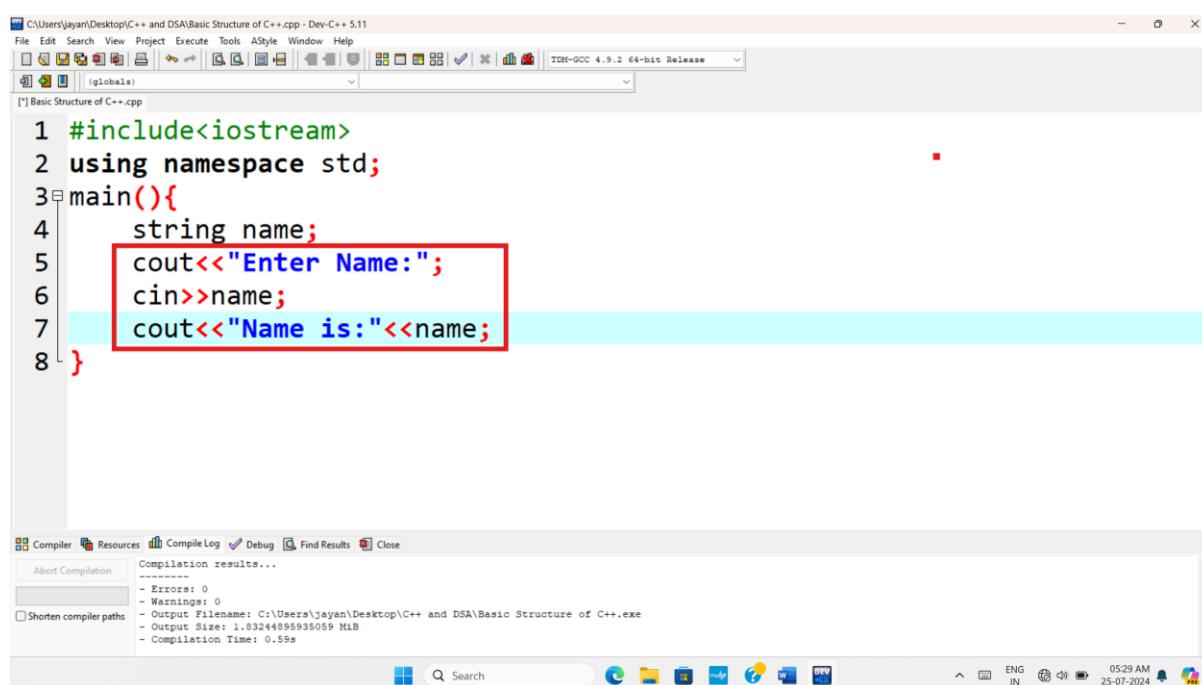

Syntax:

cin>>input_variable;

cout<<" Any type of string write in this but in inside of double column";

or

cout<<"Any type of string"<<output_variable;

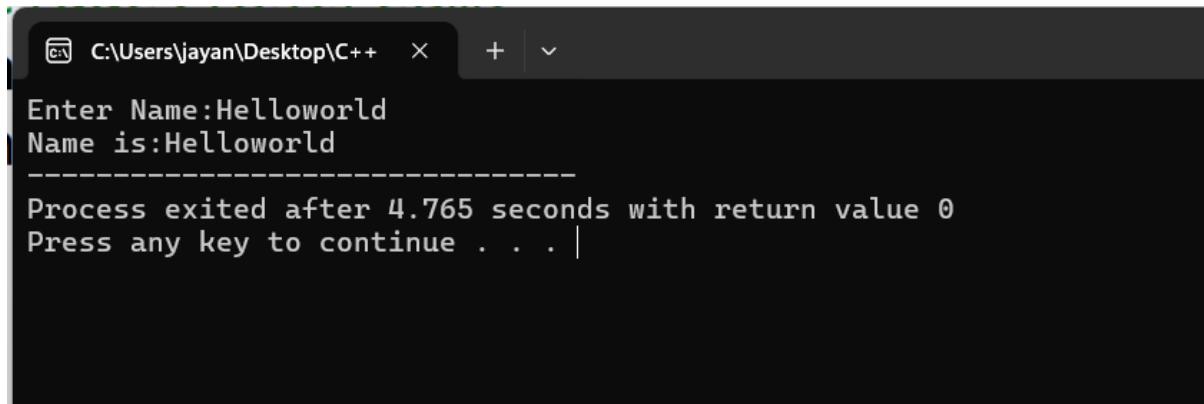

The screenshot shows the Dev-C++ IDE interface. The code editor window displays the following C++ code:

```
1 #include<iostream>
2 using namespace std;
3 main(){
4     string name;
5     cout<<"Enter Name:"; // Line 5 is highlighted with a red box
6     cin>>name;
7     cout<<"Name is:"<<name;
8 }
```

The code uses standard input-output streams (cin and cout) to interact with the user. The line `cout<<"Enter Name:";` is highlighted with a red box, indicating it is the focus of the discussion. The Dev-C++ interface includes a toolbar, menu bar, and status bar at the bottom.

Output:

```
C:\Users\jayan\Desktop\C++ + v
Enter Name:Helloworld
Name is:Helloworld
-----
Process exited after 4.765 seconds with return value 0
Press any key to continue . . . |
```

Comments

- (i) Comments is very important part of C++. Comments are used for explaining the source code and its added inside of C++ file.
- (ii) It is basically designed for developers not a user.
- (iii) C++ file can't give permission for execution of comments.
- (iv) There are two types of comments in C++:

1. Single Line Comments
2. Multiline Comments

1. Single Line Comments:

Single line comments are used for single line. If you write some un-executable source code in single line using double slashes(//) is known as single line comments.

Syntax:

```
// This is Single line Comment
```

2. Multi-Line Comments:

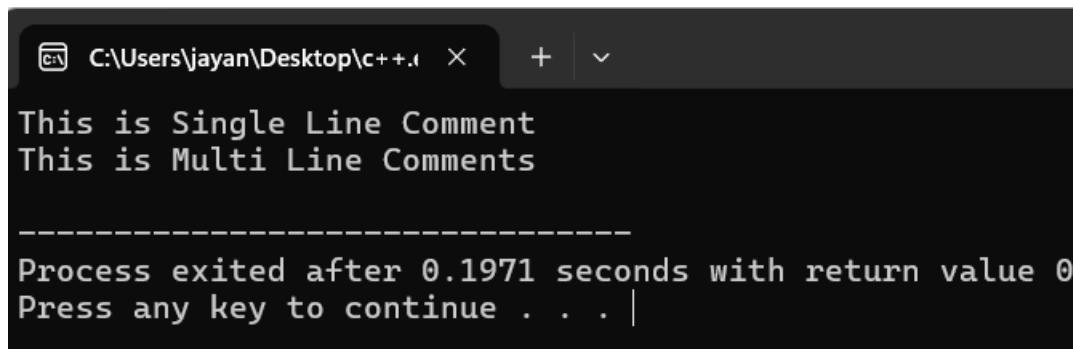

Multiline Comment are used for comments in multiple lines. If you write some un-executable source code in multiple lines using (slashes and astrick) is known as multi-line comments.

Syntax:

```
/* Multi Line Comments */
```

```
c++.cpp
1 #include<iostream>
2 using namespace std;
3 //Main Function
4 main(){
5     cout<<"This is Single Line Comment" << endl;
6     //Single Line Comments
7
8     cout<<"This is Multi Line Comments" << endl;
9     /*
10    Multi Line Comments
11 */
12 }
```

Output:

```
C:\Users\jayan\Desktop\c++.i + v
This is Single Line Comment
This is Multi Line Comments

-----
Process exited after 0.1971 seconds with return value 0
Press any key to continue . . . |
```

Keywords

- (i) In the C++ programming language, there are 95 keywords. All 95 keywords have their meaning which is already known to the compiler.
- (ii) Keywords are the reserved words with predefined meaning which are already known to the compiler.
- (iii) Whenever C++ compiler comes across a keyword, automatically it understands its meaning.

Properties of keywords

- (i) All the keywords in C++ programming language are defined as lowercase letters, so they must be used only in lowercase letters.
- (ii) Every keyword has a specific meaning, users cannot change that meaning.
- (iii) Keywords cannot be used as user-defined names like variable, functions, arrays, pointers, etc.
- (iv) Every keyword of C++ represents something or specifies some kind of an action to be formed by the compiler.

List of Keywords:

asm	double	New	switch
auto	else	operator	template
break	enum	private	this
case	extern	protected	throw
Catch	float	public	try
char	for	register	typedef
class	friend	return	union
const	goto	short	unsigned
continue	if	signed	virtual
default	inline	sizeof	void
delete	int	static	volatile
do	long	struct	while

The screenshot shows the Dev-C++ IDE interface. The top window displays the code for a C++ program named 'Basic Structure of C++.cpp'. The code includes an include directive for `<iostream>`, a `using namespace std;` directive, a `main()` function, and a cout statement that outputs the size of an integer variable. The bottom window shows the 'Compiler' tab of the results panel, which displays the compilation results, including the output filename (C:\Users\jayan\Desktop\C++ and DSA\Basic Structure of C++.exe), output size (1.83196067810059 MiB), and compilation time (0.34s). The code and compiler results are highlighted with red boxes.

```
1 #include<iostream>
2 using namespace std;
3 main(){
4     int num;
5     cout<<"Size is:"<<sizeof(num);
6 }
```

Compiler Resources Compile Log Debug Find Results Close

Compilation results...

- Errors: 0
- Warnings: 0

Output Filename: C:\Users\jayan\Desktop\C++ and DSA\Basic Structure of C++.exe

Output Size: 1.83196067810059 MiB

Compilation Time: 0.34s

Output:

The screenshot shows a terminal window with the title bar 'C:\Users\jayan\Desktop\C++'. The window displays the output of the previously compiled program. It shows the string 'Size is:4' followed by a dashed line, the message 'Process exited after 0.1827 seconds with return value 0', and the prompt 'Press any key to continue . . . |'.

```
Size is:4
-----
Process exited after 0.1827 seconds with return value 0
Press any key to continue . . . |
```

Identifiers

An identifier is a collection of characters which acts as the name of variable, function, array, pointer, structure, etc.

Rules for creating an identifier

- (i) An identifier can contain letters (upper and lower case), numerics & underscore symbol only.
- (ii) An identifier should not start with a numerical value. It can start with a letter or an underscore.
- (iii) We should not use any special symbol in between the identifier even whitespace. However, the only underscore symbol is allowed.
- (iv) Keywords shouldn't be used as identifier.
- (v) An identifier must be unique in its scope.

The screenshot shows the Dev-C++ IDE interface. The code editor window displays a C++ file named "Basic Structure of C++.cpp". The code defines a function `sum_of_two_numbers` and calls it from the `main` function. The line `cout<<"Sum of two numbers is:"<<sum;` is highlighted in blue. The `sum_of_two_numbers` function is highlighted with a red rectangle.

```
1 #include<iostream>
2 using namespace std;
3
4 //Creating a function for sum of two numbers
5 int sum_of_two_numbers(int num1,int num2){
6     int sum=num1+num2;
7     cout<<"Sum of two numbers is:"<<sum;
8     return 0;
9 }
10
11 main(){
12     //Function Calling
13     sum_of_two_numbers(20,10);
14 }
```

The compiler log window shows the compilation results for the file. It indicates 0 errors and 0 warnings, and provides details about the output file and compilation time.

Compilation results...

- Errors: 0
- Warnings: 0
- Output Filename: C:\Users\jayan\Desktop\C++ and DSA\Basic Structure of C++.exe
- Output Size: 1.83250904083252 MiB
- Compilation Time: 0.69s

Line: 14 Col: 2 Sel: 0 Lines: 14 Lenath: 272 Insert Done parsing in 0.016 seconds

Output

The terminal window displays the output of the compiled program. It shows the sum of the numbers 20 and 10, which is 30. The program then exits after 0.1937 seconds.

```
C:\Users\jayan\Desktop\C++ Sum of two numbers is:30
-----
Process exited after 0.1937 seconds with return value 0
Press any key to continue . . .
```

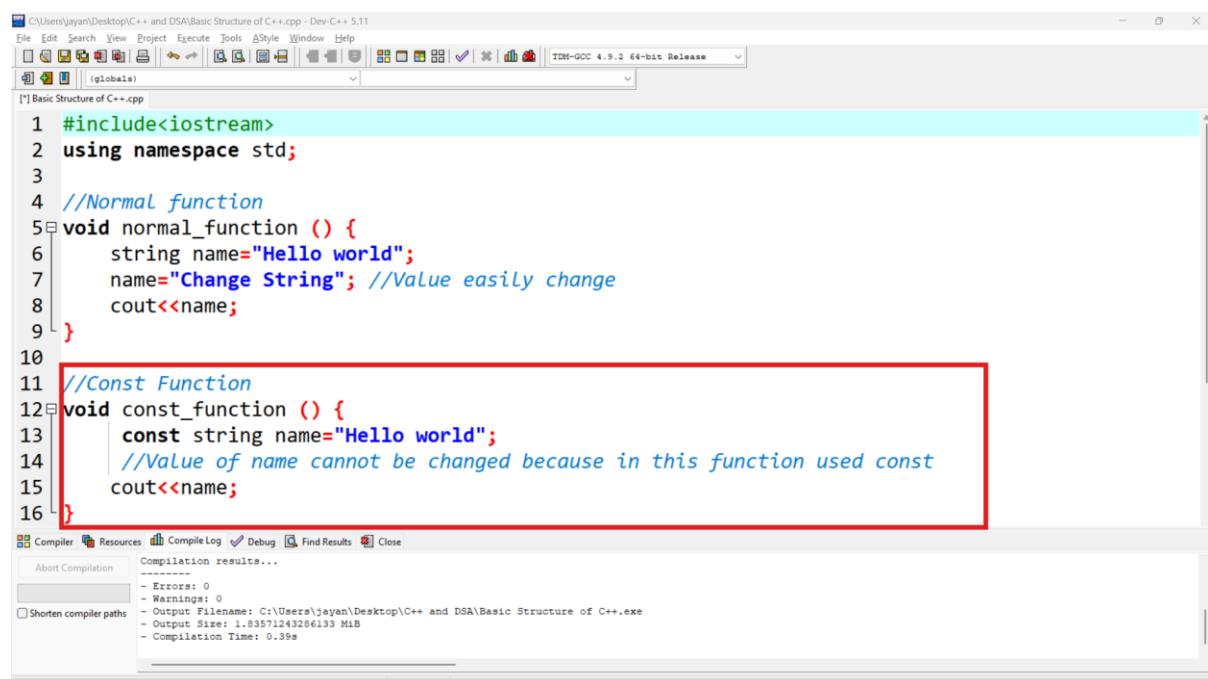

Constants

(i) A constant is a named memory location which holds only one value throughout the program execution.

(ii) In C++ programming, a constant can be of any data types like: int, float, char, string, double.

Syntax:

```
const datatype variable _ name;
```

The screenshot shows the Dev-C++ IDE interface with the following code in the editor:

```
1 #include<iostream>
2 using namespace std;
3
4 //Normal function
5 void normal_function () {
6     string name="Hello world";
7     name="Change String"; //Value easily change
8     cout<<name;
9 }
10
11 //Const Function
12 void const_function () {
13     const string name="Hello world";
14     //Value of name cannot be changed because in this function used const
15     cout<<name;
16 }
```

The code illustrates two functions: `normal_function` and `const_function`. The `normal_function` demonstrates how the value of a variable can be modified within its scope. The `const_function` is highlighted with a red box and shows a compilation error because it attempts to modify a constant variable (`name`). The IDE's status bar at the bottom indicates a compilation error with 1 error and 0 warnings.

```
16 }
17
18 //main function
19 main(){
20     normal_function();
21     cout<<endl;
22     const_function();
23 }
24
```

Datatypes

In C++ programming, each variable or constant or array must have a data type and this type specifies how much memory is to be allocated and what type of values are to be stored in that variable, constant or array.

Integer Data Types: The integer datatype is a set of whole numbers. Every integer value does not have the decimal value. We use the keyword ‘int’ to represent integer data type in C. We use the keyword int to declare the variables and to specify the return type of a function.

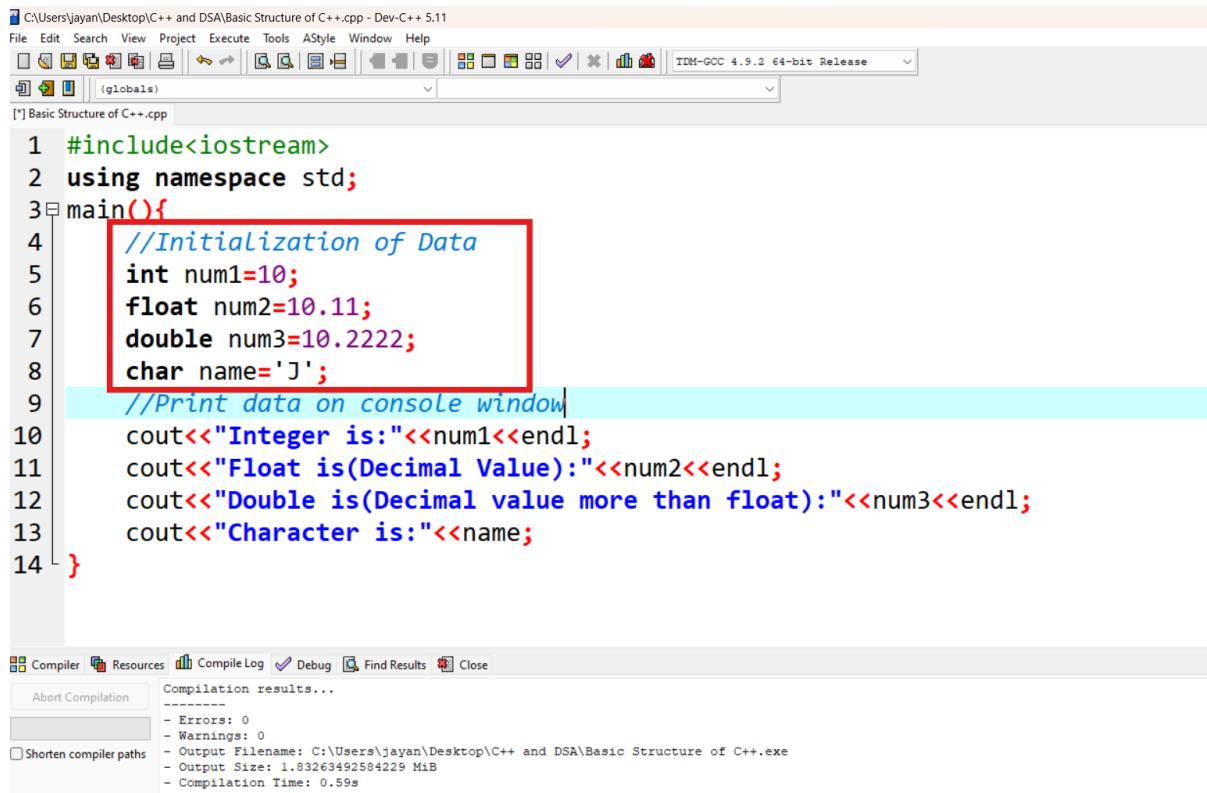

```
int x;
```

Float Data Types: Floating point data types are a set of numbers with the decimal value. Every floating-point value must contain the decimal value. The floating points data type has two variants.

- (i)float
- (ii)double

We can use the keyword “float” to represent floating point datatype and “double” to represent double datatype in C++. Both float and double are similar but they differ in the number of decimal places. The float value contains 6 decimal places whereas double value contains 15 decimal places.

Character Data Types: The Character data type is a set of characters enclosed in single quotes.

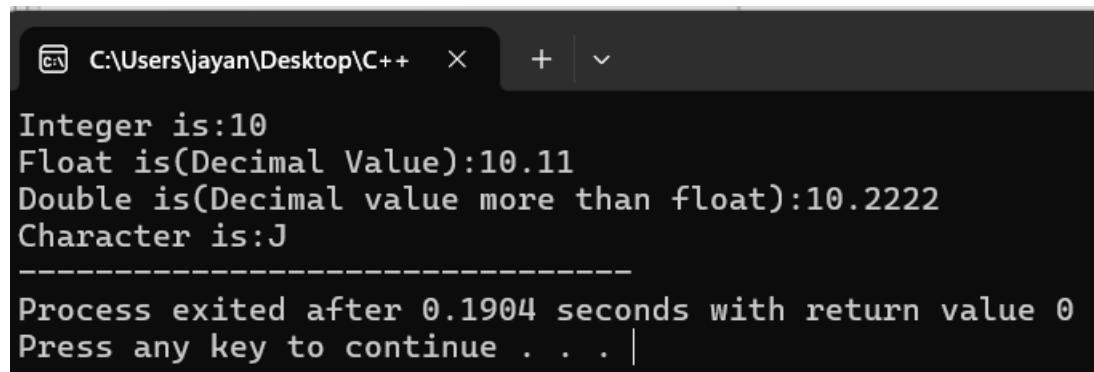

The screenshot shows the Dev-C++ IDE interface. The code editor window displays the following C++ code:

```
1 #include<iostream>
2 using namespace std;
3 int main(){
4     //Initialization of Data
5     int num1=10;
6     float num2=10.11;
7     double num3=10.2222;
8     char name='J';
9     //Print data on console window
10    cout<<"Integer is:"<<num1<<endl;
11    cout<<"Float is(Decimal Value):"<<num2<<endl;
12    cout<<"Double is(Decimal value more than float):"<<num3<<endl;
13    cout<<"Character is:"<<name;
14 }
```

The code uses `#include<iostream>` to include the standard input-output library. It defines a namespace `std`. The `main()` function initializes variables `int num1=10;`, `float num2=10.11;`, `double num3=10.2222;`, and `char name='J';`. It then prints the values of these variables to the console using `cout`. The variable `name` is printed as a character. The code is highlighted with syntax coloring: `#include`, `using`, `int`, `float`, `double`, and `char` are in blue; strings and comments are in green; operators like `=` and `<<` are in black; and numbers are in black. A red box highlights the initialization section of the code. Below the code editor is the compiler output window titled "Compilation results...". It shows the following information:

- Errors: 0
- Warnings: 0
- Output Filename: C:\Users\jayan\Desktop\C++ and DSA\Basic Structure of C++.exe
- Output Size: 1.83263492584229 MiB
- Compilation Time: 0.59s

Output:

The screenshot shows a terminal window with the title bar "C:\Users\jayan\Desktop\C++". The window displays the following text:

```
Integer is:10
Float is(Decimal Value):10.11
Double is(Decimal value more than float):10.2222
Character is:J
-----
Process exited after 0.1904 seconds with return value 0
Press any key to continue . . . |
```

The output consists of four lines of text: "Integer is:10", "Float is(Decimal Value):10.11", "Double is(Decimal value more than float):10.2222", and "Character is:J". A horizontal dashed line follows the third line. At the bottom, it says "Process exited after 0.1904 seconds with return value 0" and "Press any key to continue . . . |".

Formula used to calculate range of datatypes:

Signed: -2^{x-1} to $+2^{x-1}-1$

Unsigned: 0 to 2^x-1

Note: Where (x) is the number of bits used to store data.

Example: 2^{16}

Signed: -2^{16-1} to $+2^{16-1}-1$

$-2^{16}-1$ to $2^{16-1}-1$

-2^{15} to $2^{15}-1$

-32768 to 32768-1

-32768 to 32767

Unsigned: 0 to $2^{16}-1$

0 to $2^{16}-1$

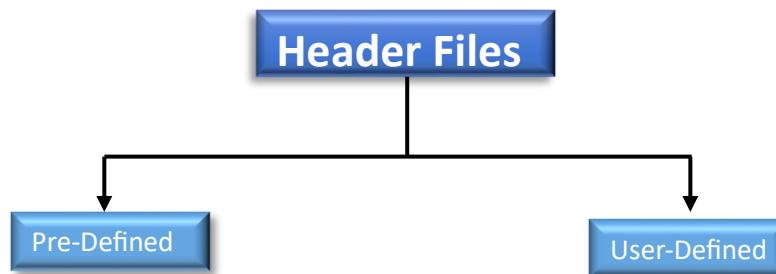

0 to 65536-1

0 to 65535

Note: Derived and User-Defined data types are explained separately because they carry lot of functionality and huge amount of data.

Header Files and its types

- (i) C++ has numerous libraries that include pre-defined functions to make programming easier.
- (ii) In C++, header files contain the set of predefined standard library functions. It's use "#include".
- (iii) All the header files have a ".h" extension.
- (iv) These preprocessor directives are used for instructing compiler that these files need to be processed before compilation.
- (v) In C++ source code should necessarily contain the header file which stands for standard input and output used to take input with the help of cout or cin function respectively.

Pre-Defined Header files: (i) Files which are already available in C++ compiler we just need to import them.

- (ii) User cannot change pre-defined function because functions already are in pre-defined header files but values of functions are change easily.
- (iii) There are various types of header files present in C++ like: <string.h>, <iostream.h>, <vector.h>, <conio.h>, and so on.

The screenshot shows the Dev-C++ IDE interface. The menu bar includes File, Edit, Search, View, Project, Execute, Tools, AStyle, Window, Help, and TDM-GCC 4.9.2 64-bit Release. The toolbar contains various icons for file operations like Open, Save, Print, and Build. The main editor window displays the following C++ code:

```
1 #include<iostream>
2 #include<string.h>
3
4 using namespace std;
5
6 main(){
7     char name1[6] = "Hello";
8     char name2[6] = "World";
9
10    //Merge two strings using string concatenation function(strcat)
11    string add_string = strcat(name1, name2);
12    cout << "Merge of two strings is:" << add_string << endl;
13
14    //Find Length of the string using string Length function(strlen)
15    char name3[15] = "Hello World";
16    cout << "Length of String is:" << strlen(name3);
}
```

The code uses `strcat` to merge two character arrays and `strlen` to find the length of a character array. The `add_string` variable and the call to `strlen` are highlighted with red boxes.

The status bar at the bottom shows Line: 10, Col: 20, Sel: 0, Lines: 16, Length: 432, Insert, and Done parsing in 0.015 seconds.

Output:

The terminal window shows the following output:

```
C:\Users\jayan\Desktop\C++ X + | v
Merge of two strings is:HelloWorld
Length of String is:11
-----
Process exited after 0.1998 seconds with return value 0
Press any key to continue . . . |
```

User-defined Header File:(i) These files are defined by the user and can be import using “#include”.

(ii)User easily create own functions for reusability of code.

(iii)It decrease the length of code.

(iv) For create user defined header file use (.h) extension.

(v) Don’t use main function for create user-defined header file.

(vi)When import the header file in main file of C++ then use double quotes (“ ”) for use of pre-defined header file functions.

Steps for creating user-defined header file:

User defined header file using (.h) extension

Step1: Include necessary predefined header file have need for our source code like: <iostream>

Step2: Write using namespace std;

Step3: Create functions

Step4: Save file with .h extension

Main file using (.cpp) extension

Step1: Import iostream header file or user defined header file using “ ” double quotes.

Step2: Write using namespace std;

Step3: Make main function for execution of source code.

Step4: Call user-defined functions.

Step5: Save the file using (.cpp) extension

Source code of user-defined header file

S

The screenshot shows the Dev-C++ IDE interface. The top menu bar includes File, Edit, Search, View, Project, Execute, Tools, AStyle, Window, and Help. The toolbar below has various icons for file operations like Open, Save, Print, and Build. The status bar at the bottom shows Line: 9, Col: 5, Sel: 0, Lines: 40, Length: 806, Insert, and Done parsing in 0.016 seconds.

```
1 #include<iostream>
2 using namespace std;
3
4 //User-Defined Function
5 void calculator (float num1,float num2,char op) {
6     //Variables Declaration
7     float add,sub,multi,div;
8     int mod;
9
10    //Use switch case
11    switch(op){
12        case '+':
13            add=num1+num2;
14            cout<<"Addition of two numbers is:"<<add<<endl;
15            break;
16    }
```

Compilation results...

```
-----
- Errors: 0
- Warnings: 0
- Output Filename: C:\Users\jayan\Desktop\C++ and DSA\Basic Structure of C++.exe
- Output Size: 1.83316993713379 MiB
- Compilation Time: 0.36s
```

The screenshot shows the Dev-C++ IDE interface. The main window displays a C++ code editor with the following content:

```
13     add=num1+num2;
14     cout<<"Addition of two numbers is:"<<add<<endl;
15     break;
16
17     case '-':
18     sub=num1-num2;
19     cout<<"Subtraction of two numbers is:"<<sub<<endl;
20     break;
21
22     case '*':
23     multi=num1*num2;
24     cout<<"Multiplication of two numbers is:"<<multi<<endl;
25     break;
26
27     case '/':
28     div=num1/num2;
```

The code implements a switch statement for addition, subtraction, multiplication, and division of two numbers. The current line of code being edited is line 27, which starts with "case '/':".

Below the code editor is the Compiler tab of the IDE, showing the compilation results:

Compilation results...

Source code of Main file

The screenshot shows the Dev-C++ IDE interface. The title bar reads "C:\Users\jayan\Desktop\C++ and DSA\Basic Structure of C++.cpp - Dev-C++ 5.11". The menu bar includes File, Edit, Search, View, Project, Execute, Tools, AStyle, Window, and Help. The toolbar contains various icons for file operations like Open, Save, Print, and Build. The status bar at the bottom shows "Line: 5 Col: 39 Sel: 0 Lines: 18 Length: 322 Insert Done parsing in 0.016 seconds". The code editor window displays the following C++ code:

```
1 #include<iostream>
2 #include"user_defined_header_file.h"
3 using namespace std;
4 main(){
5     // Function calling according to need
6     calculator(20.5,10.5,'+');
7
8     calculator(20.5,10.5,'-');
9
10    calculator(20.5,10.5,'*');
11
12    calculator(20.5,10.5,'/');
13
14    calculator(22.5,10.5,'%');
15
16    calculator(22.5,10.5,'@');
17 }
```

The code uses color coding for syntax: green for comments, red for strings and operators, and black for identifiers. Line 5 is highlighted in blue, indicating it is the current line of execution.

Output:

```
C:\Users\jayan\Desktop\C++ + ^  
Addition of two numbers is:31  
Subtraction of two numbers is:10  
Multiplication of two numbers is:215.25  
Division of two numbers is:1.95238  
Remainder of two numbers is:2  
Please Enter Valid Operator  
-----  
Process exited after 0.1676 seconds with return value 0  
Press any key to continue . . . | .
```

Functions and its types

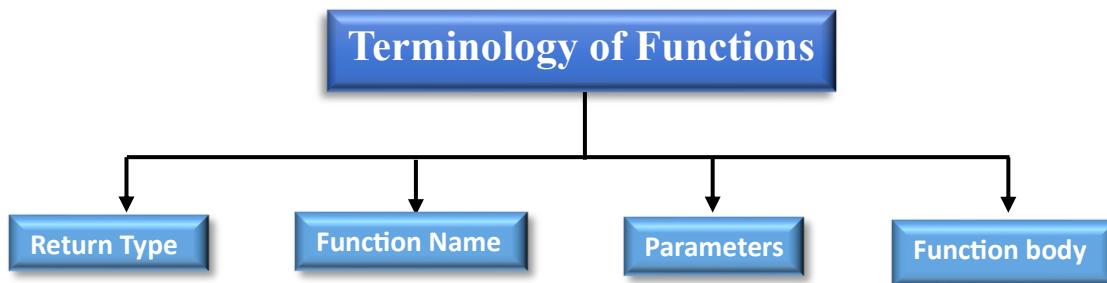

- (i)A function is a group of statement that together perform a task. Every C++ program atleast one function, which is main(), and all the most trivial program can define additional functions.
- (ii)You can divide up your code into separate functions. How can you divide up your code among different functions is up to you, but logically the division is much that each function perform a specific task.
- (iii)A function declaration tells the compiler about a function's name, return type and parameters. A function definition provides the actual body of function.
- (iv)The C++ standard library provides numerous build-in functions that your program can call.

Ex: cout<< for output, strcat() for string concatenation, etc.

- (v)A function can also be referred as a method or a sub-routine or a procedure etc.

Syntax:

```
return-type function name(parameter list)
{
    //body of code
}
```

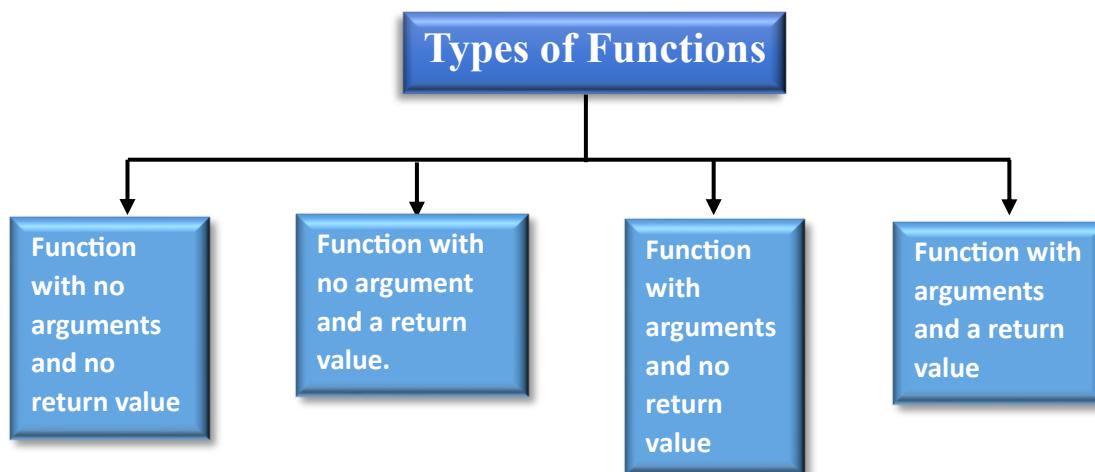

Return Type: The return type is the data type of the value the function return. Some functions perform the desired operations without returning a value. In the case, the return type is the keyword void.

Function Name: This is the actual name of the function. The function name and the parameter list together constitute the **function signature**.

Parameters: A parameter is like a place holder. When a function is invoked, you pass a value to the parameter. This value is referred to as actual parameter or argument. The parameter list refers to the type, order, and number of the parameters of a function. Parameters are optional that is a function may contain no parameters.

Function Body: The function body contains a collection of statements that define what the function does.

1.Function with no arguments and no return value:

The screenshot shows the Dev-C++ IDE interface. The top menu bar includes File, Edit, Search, View, Project, Execute, Tools, AStyle, Window, and Help. Below the menu is a toolbar with various icons. The main workspace shows a code editor with the file 'c++.cpp' open. The code contains a user-defined function 'hw' and a main function that calls it. The code is color-coded: #include<iostream> is green, using namespace std; is red, comments are blue, and the function definitions are black. The 'main()' line is highlighted in light blue. The bottom panel displays the 'Compiler' tab of the status bar, which shows the command used for compilation (g++.exe "C:\Users\jayan\Desktop\c++.cpp" -o "C:\User...") and the compilation results. The results show 0 errors and 0 warnings, with the output filename being C:\Users\jayan\Desktop\c++.exe and a compilation time of 1.47s.

```
1 #include<iostream>
2 using namespace std;
3
4 //User-defined Hello world function
5 void hw () {
6     cout<<"Hello World";
7 }
8
9 //main function
10 main(){
11     //call user defined function
12     hw();
13 }
```

Press any key to continue . . . |
```

Recursion

(i) Recursion is the process which comes into existence when a function call a copy of itself to work on a smaller problem. Any function which calls itself is called recursive function; it is important to impose a termination condition of recursion. Recursion code is shorter than iterative code.

(ii) Recursion cannot be applied to all the problem, but it is more useful for the tasks that can be defined in terms of similar subtasks.

Example: Factorial, sorting or searching etc.

The screenshot shows the Dev-C++ IDE interface. The code editor window displays a C++ program named 'c++.cpp' with the following content:

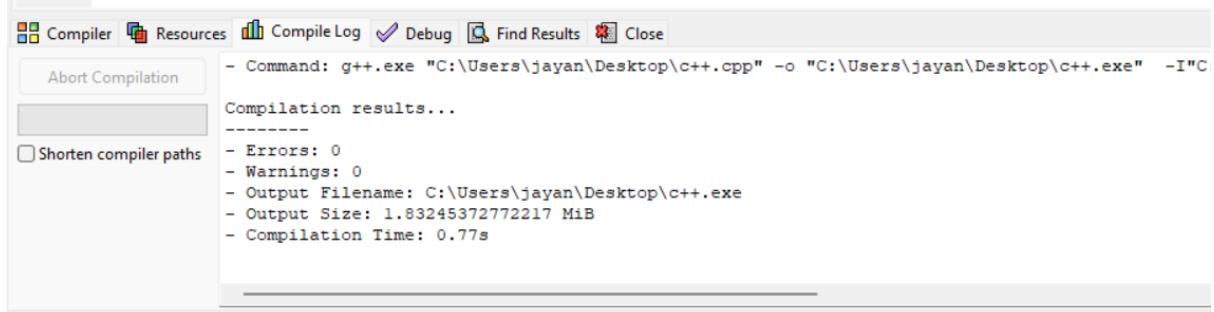

```
1 #include<iostream>
2 using namespace std;
3
4 //Function Declaration
5 int factorial(int n);
6
7 //Main function
8 int main() {
9     int n;
10    cout<<"Enter a positive integer:";
11    cin >> n;
12    cout << "Factorial of " << n << " = " << factorial(n);
13    return 0;
14 }
15
```

The 'Compile Log' tab in the bottom panel shows the compilation command and results:

```
- Command: g++.exe "C:\Users\jayan\Desktop\c++.cpp" -o "C:\Users\jayan\Desktop\c++.exe" -I"C:\Pro
Compilation results...
-----

```

At the bottom, status bar shows: Line: 16 Col: 21 Sel: 0 Lines: 22 Length: 380 Insert Done parsing in 0.016 seconds

```
12     cout << "Factorial of " << n << " = " << factorial(n);
13     return 0;
14 }
15
16 //Factorial function
17 int factorial(int n) {
18     if(n > 1)
19         return n * factorial(n - 1);
20     else
21         return 1;
22 }
```

Output:

A screenshot of a terminal window titled 'C:\Users\jayan\Desktop\c++.exe'. The window contains the following text:

```
Enter a positive integer:5
Factorial of 5 = 120
-----
Process exited after 2.22 seconds with return value 0
Press any key to continue . . . |
```

Function invoking

Functions can be invoked into two types (i)Call by Value (ii) Call by Reference. These two ways are generally differentiate by the type of values passed to them as parameters.

Actual Parameters: The parameters passed to function are called Actual parameters.

Formal Parameters: The parameters received by function are called formal parameters.

Call by Value:(i) In call by value method, the value of the actual parameters is copied into the formal parameters. In other words, we can say that value of the variable is used in the function call in the call by value method.

(ii)In call by method, we can not modify the value of the actual parameter by the formal parameter.

(iii)Different memory is allocated for actual and formal parameters since the value of the actual parameter is copied into the formal parameter.

(iv)The actual parameter is the argument which is used in the function call where as formal parameter is the argument which is used in the function definition.

A is:10
B is:20
After Swap:
A is:20
B is:10

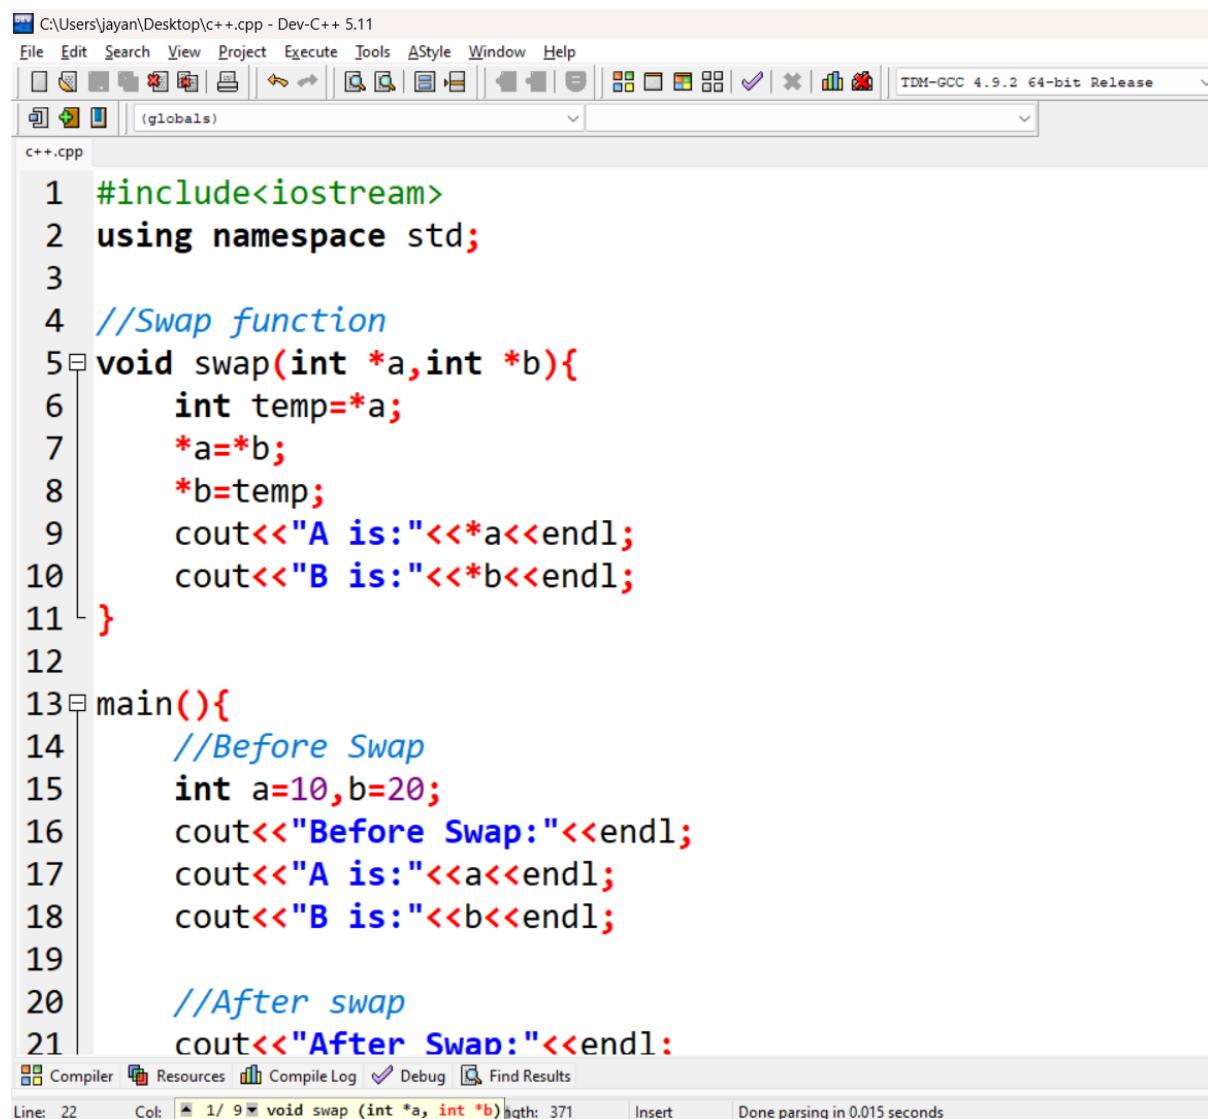

-----
Process exited after 0.6962 seconds with return value 0
Press any key to continue . . . |
```

Call by Reference:(i) In call by reference, the address of the variable is passed into the function call as the actual parameter.

(ii)The value of the actual parameters can be modified by changing the formal parameters since the address of the actual parameters is passed.

(iii)In call by reference, the memory allocation is similar for both the formal parameters and actual parameters.

All operations in the function are performed on the value stored at the address of the actual parameters, and the modified value gets stored at the same address.

The screenshot shows the Dev-C++ IDE interface with a C++ file named "c++.cpp" open. The code implements a swap function using pointers and demonstrates its use in the main function. The IDE's status bar at the bottom indicates the code has been parsed successfully.

```
1 #include<iostream>
2 using namespace std;
3
4 //Swap function
5 void swap(int *a,int *b){
6     int temp=*a;
7     *a=*b;
8     *b=temp;
9     cout<<"A is:"<<*a<<endl;
10    cout<<"B is:"<<*b<<endl;
11 }
12
13 main(){
14     //Before Swap
15     int a=10,b=20;
16     cout<<"Before Swap:"<<endl;
17     cout<<"A is:"<<a<<endl;
18     cout<<"B is:"<<b<<endl;
19
20     //After swap
21     cout<<"After Swap:"<<endl;
```

```
18     cout<<"B is:"<<b<<endl;
19
20 //After swap
21 cout<<"After Swap:"<<endl;
22 swap(&a,&b);
23 }
```

▲ 1/ 9 ▾ void swap (int *a, int *b)

Special Symbols

C++ supports a rich set of special symbols that include symbols to perform mathematical operations, to check condition, whitespaces, backspaces, or other special symbols.

Ex: #, @, %, (), { }, etc

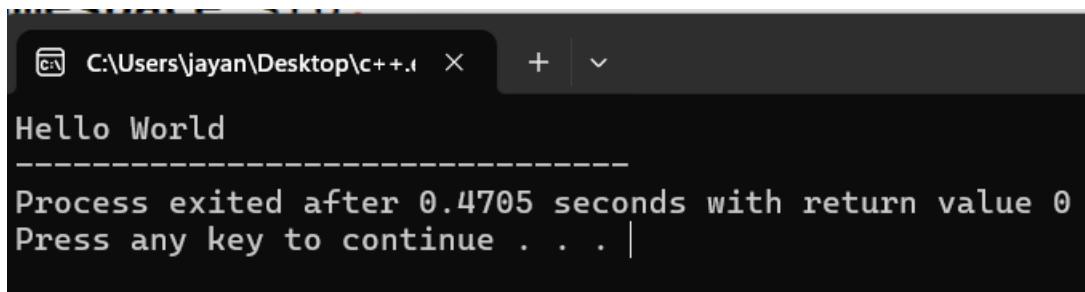

The screenshot shows a code editor window with a file named "c++.cpp". The code is as follows:

```
1 #include<iostream>
2 using namespace std;
3 //main function
4 //Special symbols:(),{},[],!,?,~,...
5 main()
6 {
7     cout<<"Hello World";
}
```

Red boxes highlight several special symbols: the opening parenthesis in "main()", the opening brace in the block, the closing brace at the end of the function, and the double less-than operator in "cout<<".

Output:

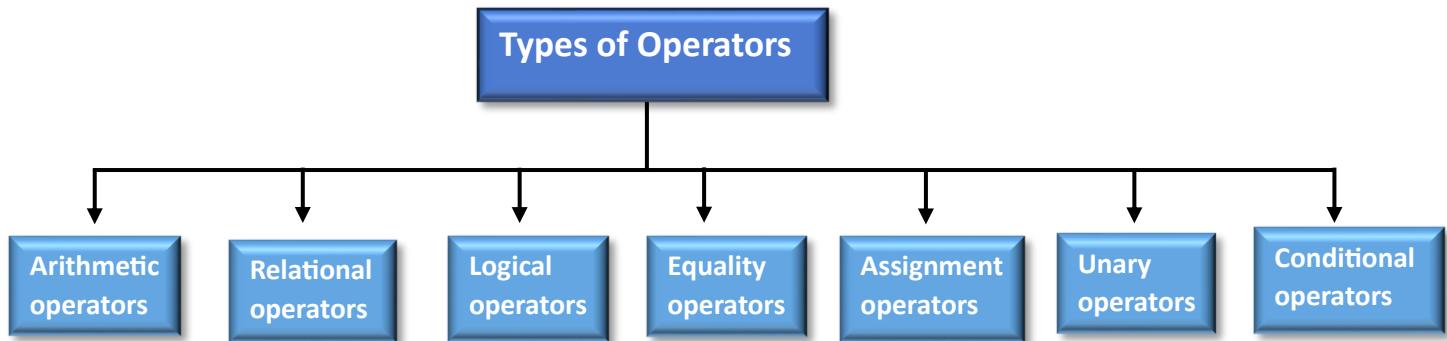

The screenshot shows a terminal window with the following output:

```
C:\Users\jayan\Desktop\c++.i  X + - 
Hello World
-----
Process exited after 0.4705 seconds with return value 0
Press any key to continue . . . |
```

Operators

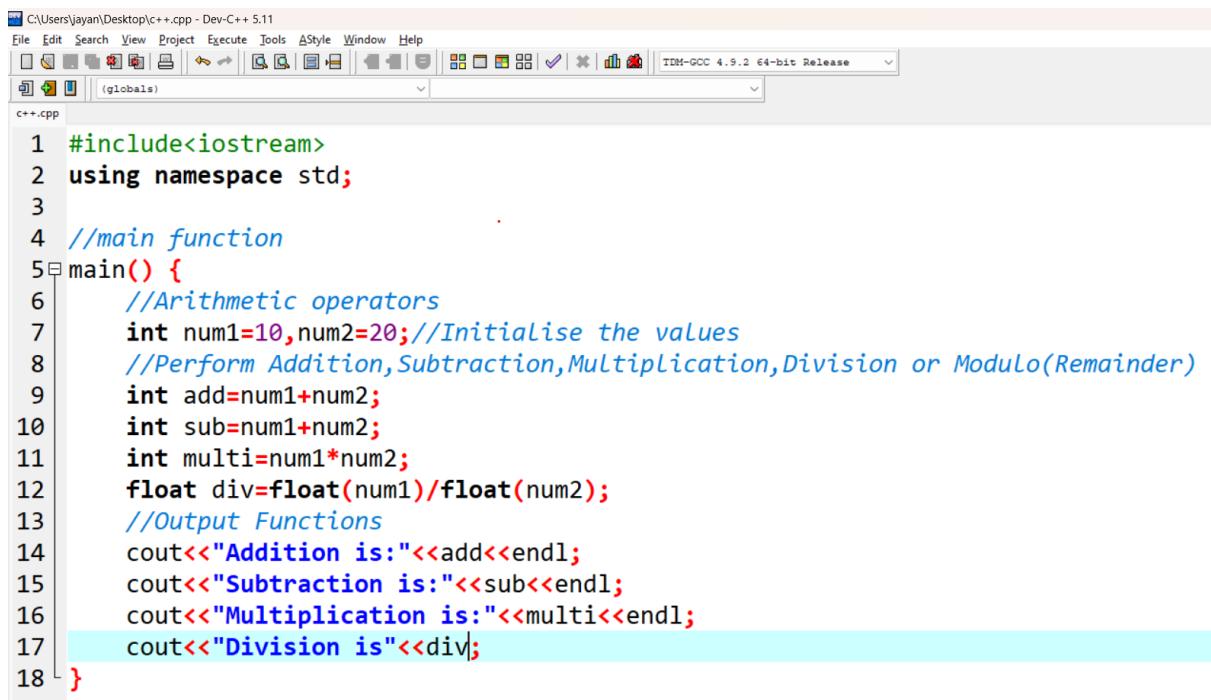

An operator is a symbol that tells the compiler to perform specific mathematical or logical functions. C++ language is rich in build in operators.

Arithmetic Operators:

An arithmetic operators are performs mathematical operations such as addition, subtraction, multiplication or division etc.

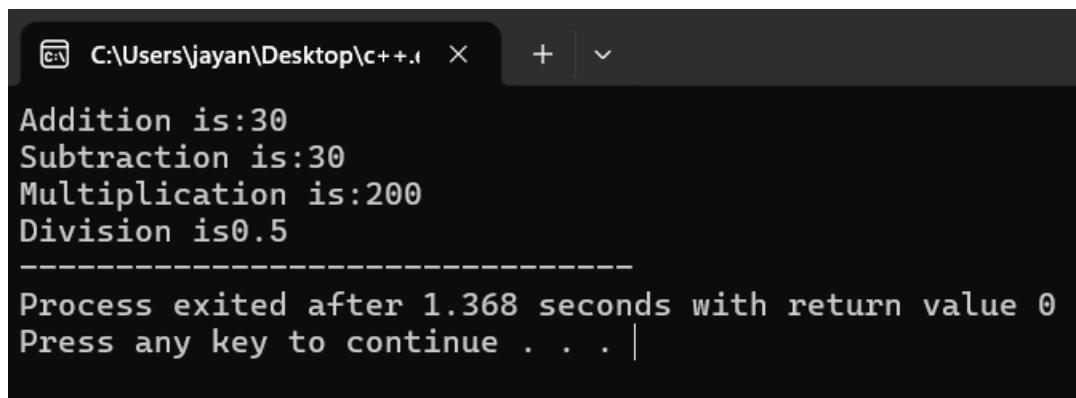

Operators	Description
+	Addition
-	Subtraction
*	Multiplication
/	Division
%	Modulo(Remainder)

The screenshot shows the Dev-C++ IDE interface. The title bar reads "C:\Users\jayan\Desktop\c++.cpp - Dev-C++ 5.11". The menu bar includes File, Edit, Search, View, Project, Execute, Tools, AStyle, Window, and Help. The toolbar contains various icons for file operations like Open, Save, Print, and Build. The status bar at the bottom right says "TDM-GCC 4.9.2 64-bit Release". The code editor window displays the following C++ code:

```
1 #include<iostream>
2 using namespace std;
3
4 //main function
5 main() {
6     //Arithmetic operators
7     int num1=10,num2=20;//Initialise the values
8     //Perform Addition,Subtraction,Multiplication,Division or Modulo(Remainder)
9     int add=num1+num2;
10    int sub=num1-num2;
11    int multi=num1*num2;
12    float div=float(num1)/float(num2);
13    //Output Functions
14    cout<<"Addition is:"<<add<<endl;
15    cout<<"Subtraction is:"<<sub<<endl;
16    cout<<"Multiplication is:"<<multi<<endl;
17    cout<<"Division is"<<div;
18 }
```

Output:

The terminal window shows the output of the executed C++ program. The output is:

```
Addition is:30
Subtraction is:30
Multiplication is:200
Division is0.5
-----
Process exited after 1.368 seconds with return value 0
Press any key to continue . . . |
```

Relational Operator:

A relational operator checks the relationship between two operands. If the relation is true, it return 1; if the relation is false, it return 0.

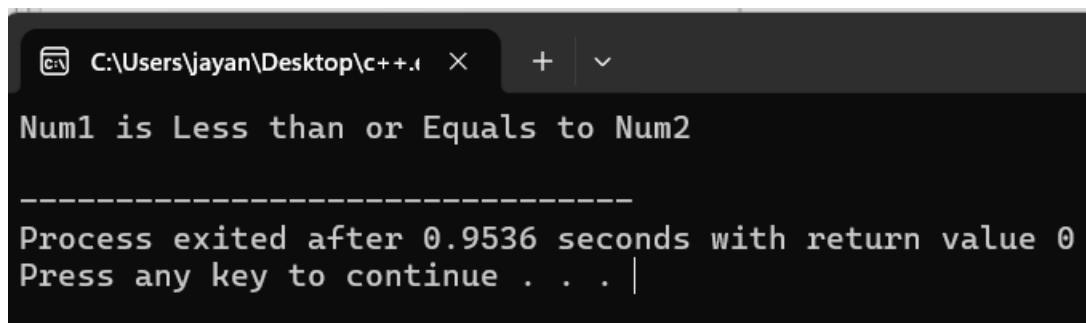

Relational operator are used for decision making and loops.

Operators	Description
>	Greater Than
<	Less Than
>=	Greater than equals to
<=	Less Than equals to
==	Equals to
!=	Not Equals to

```
#include<iostream>
using namespace std;

//main function
main() {
    //Relational operators
    int num1=10,num2=20;//Initialise the values
    //Conditions
    if(num1 > num2){
        cout<<"Num1 is Greater than Num2" << endl;
    }
    if(num1 <= num2){
        cout<<"Num1 is Less than or Equals to Num2" << endl;
    }
}
```

Output:

A screenshot of a terminal window titled "C:\Users\jayan\Desktop\c++.i". The window contains the following text:
Num1 is Less than or Equals to Num2

Process exited after 0.9536 seconds with return value 0
Press any key to continue . . . |

Logical operator:

An expression containing logical operator returns either 0 or 1 depending upon whether expression results true or false. Logical operator are commonly used in decision making in C++ programming.

Operators	Description
&&	Logical And
	Logical OR
!	Logical Not

Note: (i) $!(!=5)$: If Not Equals to is in brackets and not operator are also in outside the brackets, so situation will be opposite(Not operator cannot be work).

$(!=5) : 0$

$!(!=5) : 1$

```
#include<iostream>
using namespace std;

//main function
main() {
    //Logical operators
    int num1=10,num2=20,num3=5;//Initialise the values
    //Conditions
    if(num1>num2 && num1>num3){
        cout<<"Num1 is Greater(Logical AND)"<<endl;
    }
    if(num1>num2 || num1>num3){
        cout<<"Num1 is Greater(Logical OR)"<<endl;
    }
}
```

Output:

```
C:\Users\jayan\Desktop\c++.i + ▾
Num1 is Greater(Logical OR)
-----
Process exited after 0.7145 seconds with return value 0
Press any key to continue . . . |
```

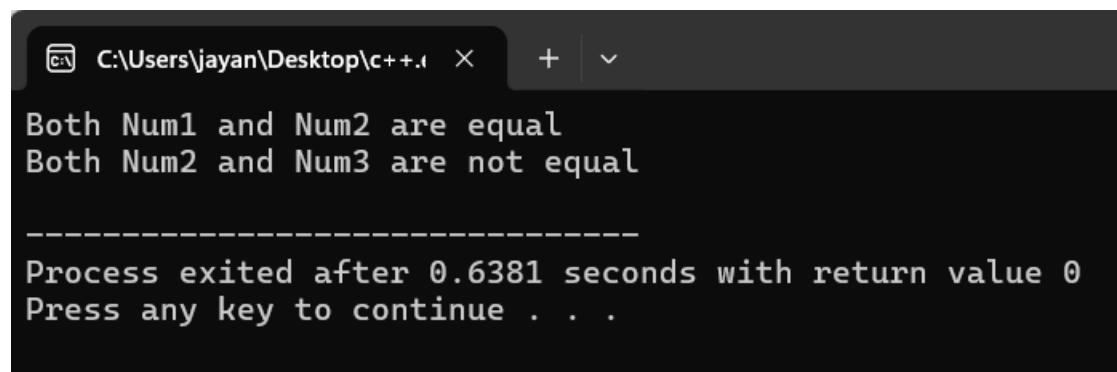

Equality operators:

- (i) `(==)`: Equals To is used to compare two values or expressions. The result is true if the expression are equal or otherwise false.
- (ii) `(!=)`: Not Equals To returns true if the operands doesn't have the same value; otherwise, it returns false.

```
#include<iostream>
using namespace std;

//main function
main() {
    //Logical operators
    int num1=10, num2=10, num3=5; //Initialise the values
    //Conditions
    if(num1==num2){
        cout<<"Both Num1 and Num2 are equal" << endl;
    }
    if(num2!=num3){
        cout<<"Both Num2 and Num3 are not equal" << endl;
    }
}
```

Output:

```
C:\Users\jayan\Desktop\c++.i + ▾
Both Num1 and Num2 are equal
Both Num2 and Num3 are not equal

-----
Process exited after 0.6381 seconds with return value 0
Press any key to continue . . .
```

Assignment operators:

An assignment operator is used for assigning a value to a variable. The most common operator is ($=$).

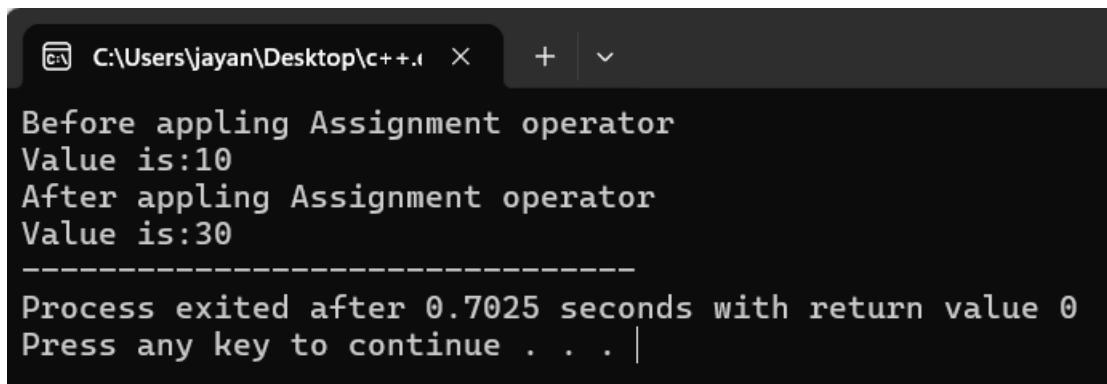

Operators	Description
$+=$	Addition or Equal To
$-=$	Subtraction or Equal To
$*=$	Multiplication or Equal To
$/=$	Division or Equal To
$\%=$	Modulo or Equal To

```
#include<iostream>
using namespace std;

//main function
main() {
    //Assignment operators
    int num1=10;//Initialise the values
    //Before applying Assignment operator
    cout<<"Before applying Assignment operator"<<endl;
    cout<<"Value is:"<<num1<<endl;
    //After applying Assignment operator
    num1 += 20;
    cout<<"After applying Assignment operator"<<endl;
    cout<<"Value is:"<<num1;

}
```

Output:

```
C:\Users\jayan\Desktop\c++.i × + | v
Before applying Assignment operator
Value is:10
After applying Assignment operator
Value is:30
-----
Process exited after 0.7025 seconds with return value 0
Press any key to continue . . . |
```

Unary Minus (--):

- (i) The minus operator changes the sign of its argument. A positive number becomes negative and a negative number becomes positive.
- (ii) Unary minus is different from subtraction operator, as subtraction requires two operands.
- (iii) $(--)$ = $--a$ or $a--$
- (iv). It is used to decrement the value of the variable one.

(i) Prefix decrement:

In this method, the operator precedes the operand (eg: $--a$). This value of operator will be altered before it is used.

(ii) Postfix decrement:

In this method, the operator follows the operand (eg: $a--$). The value of operator will be altered after it is used.

Increment (++):

It is used the value of the variable by 1.

(i)Prefix increment: In this method, the operator proceed the operand (++a). The value of operand will be altered before, it is used.

(ii)Postfix increment: In this method, the operator follows the operands(eg. a++). The value operand will be altered after it is used.

```
c++.cpp
1 #include<iostream>
2 using namespace std;
3 //Function for(++)
4 void increment(){
5     int num1=10;
6     cout<<endl<<"Simple Increment Number:"<<num1<<endl;
7     ++num1;//num1=value+1
8     cout<<"Prefix Increment Number is:"<<num1<<endl;
9     num1++;//num1=value+1
10    cout<<"Postfix Increment Number is:"<<num1<<endl;
11 }
12 //Function for(--)
13 void decrement(){
14     int num2=10;
15     cout<<endl<<"Simple Decrement Number:"<<num2<<endl;
16     --num2;//num2=value-1
17     cout<<"Prefix Decrement Number is:"<<num2<<endl;
18     num2--;//num2=value-1
19     cout<<"Postfix Decrement Number is:"<<num2<<endl;
20 }
21 //Main Function
22 main(){
23     cout<<"This is Increment Function(++):";
24     increment();
```

```
21 //Main Function
22 main(){
23     cout<<"This is Increment Function(++):";
24     increment();
25     cout<<endl;
26     cout<<"This is Decrement Function(--):";
27     decrement();
28 }
```

Output:

```
C:\Users\jayan\Desktop\c++.i + v
This is Increment Function(++):
Simple Increment Number:10
Prefix Increment Number is:11
Postfix Increment Number is:12

This is Decrement Function(--):
Simple Decrement Number:10
Prefix Decrement Number is:9
Postfix Decrement Number is:8

-----
Process exited after 0.2126 seconds with return value 0
Press any key to continue . . . |
```

Conditional operator

- (i) Conditional Operator is known as ternary operator
- (ii) It is shortest form of writing conditional statements. It can be used as an inline conditional statement in place of if-else to execute some conditional code.
- (iii) (?) or (:) these symbols are used for conditional operator.

Syntax:

Datatype variableName=Expression ? statement1:statement2;

```
c++.cpp
1 #include<iostream>
2 using namespace std;
3 //Function for Conditional Operator
4 void conditional_operator(){
5     cout<<"Value is:"<<endl;
6     for(int num=1;num<=10;num++){
7         //Conditional operator
8         string output=num==5?"This is 5":"This is not5";
9         cout<<output<<endl;
10    }
11 }
12 main(){
13     conditional_operator();
14 }
```

Output:

```
C:\Users\jayan\Desktop\c++.i + ▾
Value is:
This is not5
This is 5
This is not5
-----
Process exited after 0.2157 seconds with return value 0
Press any key to continue . . . |
```

Bitwise Operator:

To perform bit level operation in C++ programming, bitwise operator are used.

Operator	Description
&	Bitwise AND
	Bitwise OR
^	Bitwise XOR
~	Bitwise Complement
<<	Bitwise left shift
>>	Bitwise right shift

Strings

- (i)The string can be defined as the one-dimensional array of characters terminated by a null (“\0”).
- (ii)The character array or the string is used to manipulate text such as word or sentences.
- (iii)Each character in the array occupies one byte of memory, and the last character must always be 0.
- (iv)The termination character (“\0”) is important in a string since it is only way to identify where the string ends. When we defined a string as char s[10],the character s[s] is implicitly initialized with the null in the memory.

```
#include<iostream>
#include<string.h>
using namespace std;

//main function
main() {
    .
    .
    char s[20];
    cout<<"Enter String:";
    cin>>s;
    cout<<"String is:"<<s;
}
```

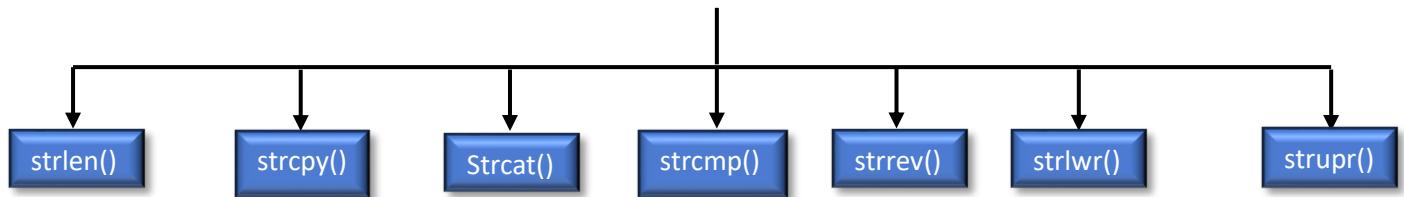

Output:

```
C:\Users\jayan\Desktop\c++.i  X + | v
Enter String:Hello
String is:Hello
-----
Process exited after 4.589 seconds with return value 0
Press any key to continue . . . |
```

String Functions

In C++ we will see how to compare two strings, Concatenate, strings, copy one string to another & perform various string manipulation operations. We can perform such operations using the pre-defined functions of “string.h” header file. In order to use these string functions, you must include string.h file in our c++ program.

Types of String Functions

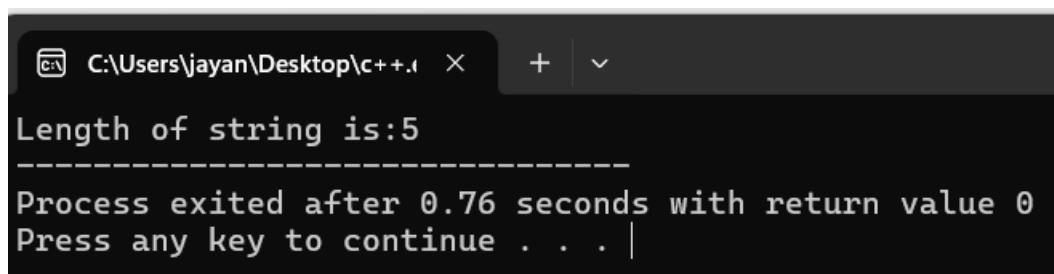

`strlen()`: The `strlen()` function return the length of the given string. It doesn't count null character '`\0`'.

```
#include<iostream>
#include<string.h>
using namespace std;

//main function
main() {
    char alphabet[10] = "Hello";
    int len = strlen(alphabet);
    cout << "Length of string is:" << len;
}
```

Output:

```
C:\Users\jayan\Desktop\c++.i x + | v
Length of string is:5
-----
Process exited after 0.76 seconds with return value 0
Press any key to continue . . . |
```

strcpy(): Copies the contents of source string to destination string.

```
#include<iostream>
#include<string.h>
using namespace std;

//main function
main() {
char alphabets1[10] = "Hello";
char alphabets2[10];
cout << "The value of Second string before apply string function:" << alphabets2 << endl;
strcpy(alphabets2, alphabets1);
cout << "The value of Second string after apply string function:" << alphabets2;
}
```

Output:

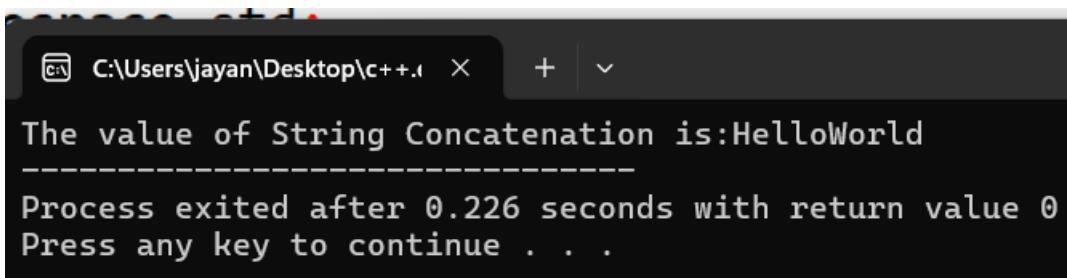

```
The value of Second string before apply string function:
The value of Second string after apply string function:Hello
-----
Process exited after 0.1725 seconds with return value 0
Press any key to continue . . . |
```

strcat(): Concatenation or join first string with second string. The result of the string is stored in first string.

```
#include<iostream>
#include<string.h>
using namespace std;

//main function
main() {
char alphabets1[10] = "Hello";
char alphabets2[10] = "World";
cout << "The value of String Concatenation is:" << strcat(alphabets1, alphabets2);
}
```

Output:

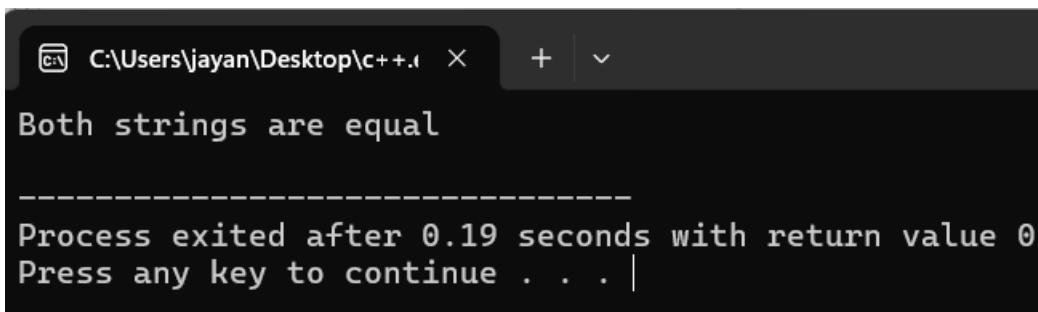

```
The value of String Concatenation is:HelloWorld
-----
Process exited after 0.226 seconds with return value 0
Press any key to continue . . .
```

strcmp(): Compare the first string with second string. If both strings are same, it returns 0.

```
#include<iostream>
#include<string.h>
using namespace std;

//main function
main() {
    char alphabets1[10]="Hello";
    char alphabets2[10]="Hello";
    if(strcmp(alphabets1,alphabets2)==0)
        cout<<"Both strings are equal"<<endl;
    else
        cout<<"Both strings are not equal";
}
```

Output:

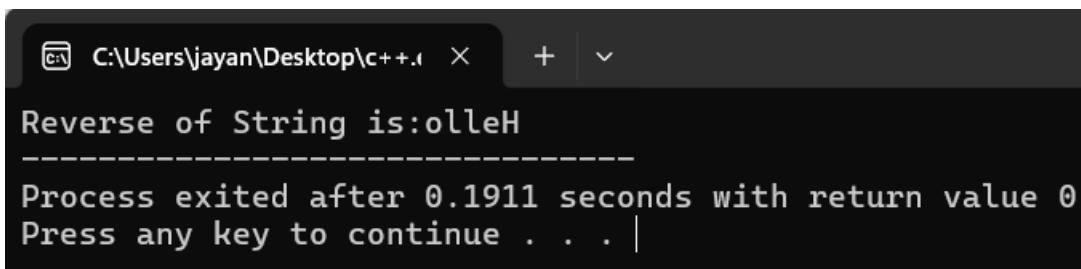

```
C:\Users\jayan\Desktop\c++.i X + | ~
Both strings are equal
-----
Process exited after 0.19 seconds with return value 0
Press any key to continue . . . |
```

strrev(): It returns reverse of the string.

```
#include<iostream>
#include<string.h>
using namespace std;

//main function
main() {
char alphabets1[10]="Hello";
cout<<"Reverse of String is:"<<strrev(alphabets1);
}
```

Output:

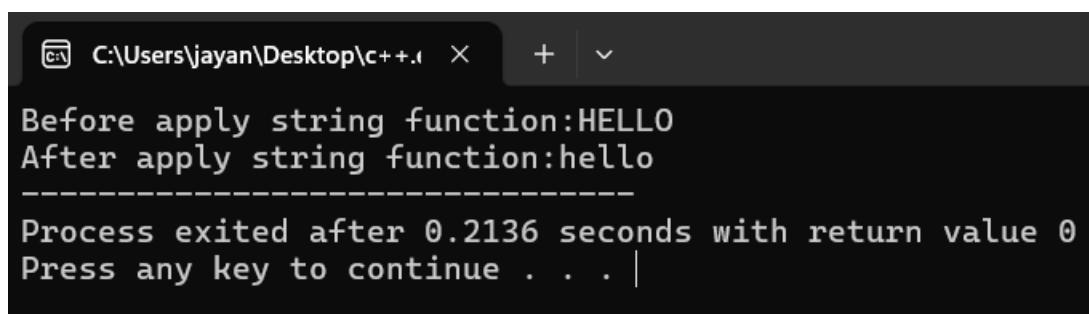

```
C:\Users\jayan\Desktop\c++.i X + | ~
Reverse of String is:olleH
-----
Process exited after 0.1911 seconds with return value 0
Press any key to continue . . . |
```

strlwr(): It returns string characters in lowercase.

```
#include<iostream>
#include<string.h>
using namespace std;

//main function
main() {
    char alphabets1[10] = "HELLO";
    cout << "Before apply string function:" << alphabets1 << endl;
    cout << "After apply string function:" << strlwr(alphabets1);
}
```

Output:

The screenshot shows a terminal window with the following text output:

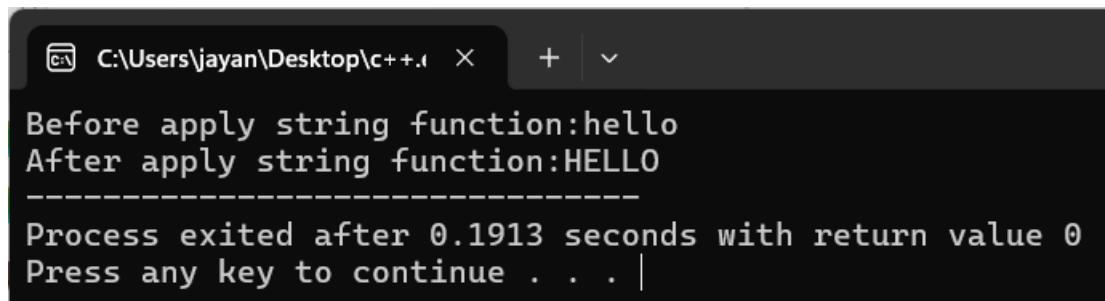

```
C:\Users\jayan\Desktop\c++.i  X  +  ▾
Before apply string function:HELLO
After apply string function:hello
-----
Process exited after 0.2136 seconds with return value 0
Press any key to continue . . . |
```

strupr(): It returns string characters in uppercase.

```
#include<iostream>
#include<string.h>
using namespace std;

//main function
main() {
char alphabets1[10]="hello";
cout<<"Before apply string function:"<<alphabets1<<endl;
cout<<"After apply string function:"<<strupr(alphabets1);
}
```

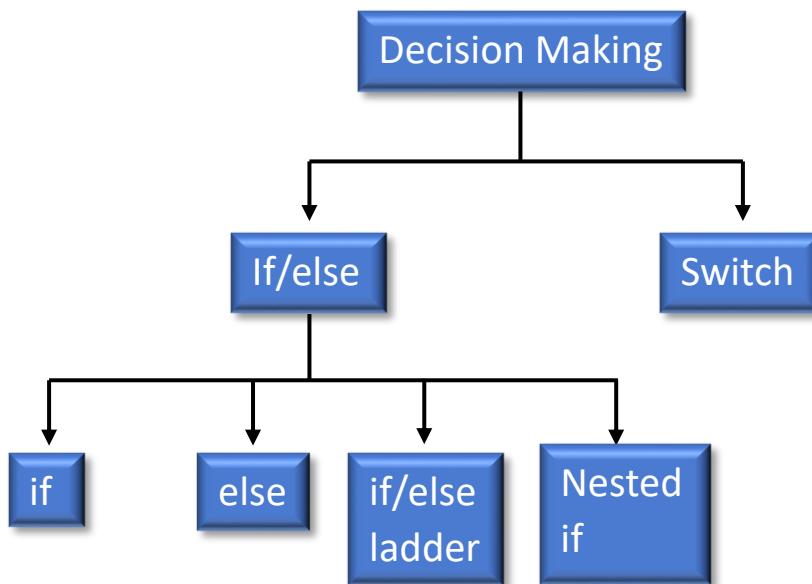

Output:

```
C:\Users\jayan\Desktop\c++.i x + v
Before apply string function:hello
After apply string function:HELLO
-----
Process exited after 0.1913 seconds with return value 0
Press any key to continue . . . | ;
```

Conditional Statement (if/else or switch)

- (i) There come situation in real life when we need to make some decision and based on these decisions, we decide that should we do next. Similar situation arise in programming also where we need to make some decision and based on these decision, we will execute the next block of code.
- (ii) Decision making statements in programming languages or C++ decides the direction of flow of program execution.
- (ii) It is also known as Decision Making statement.

If statement:

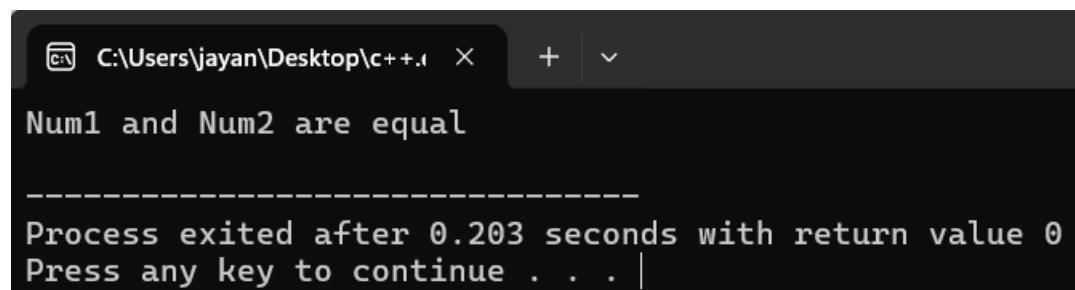

If statement is the most simple decision making statement. It is used to decide whether a certain statement or block of statement will be executed or not.

Syntax

```
If(condition){  
    Body of if statement  
}
```

```
#include<iostream>  
#include<string.h>  
using namespace std;  
  
//main function  
int main() {  
    int num1=10, num2=10;  
    if(num1==num2)  
        cout<<"Num1 and Num2 are equal"<<endl;  
}
```

Output:

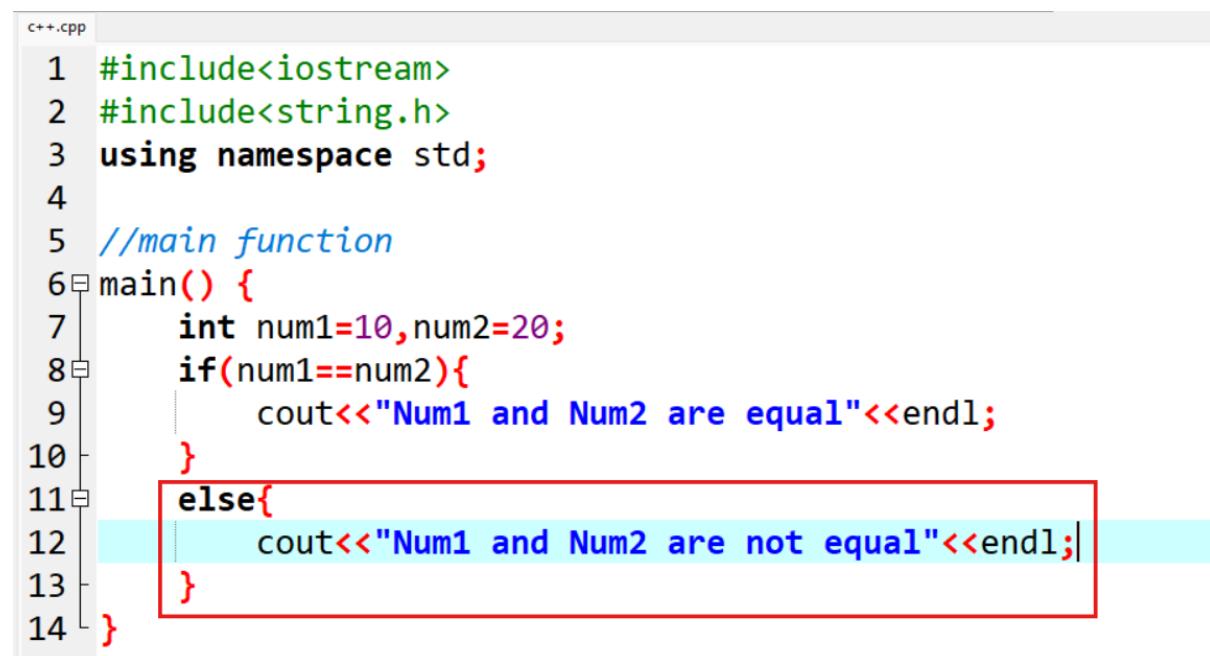

```
C:\Users\jayan\Desktop\c++.i  
Num1 and Num2 are equal  
-----  
Process exited after 0.203 seconds with return value 0  
Press any key to continue . . . |
```

If/else statement:

The if statement alone tells us that if a condition is true it will execute a block of statement and if the condition is false it won't. But if we want to do something else if the condition is false. Here comes the else statement. We can use the else statement with if statement to execute a block of code when the condition is false.

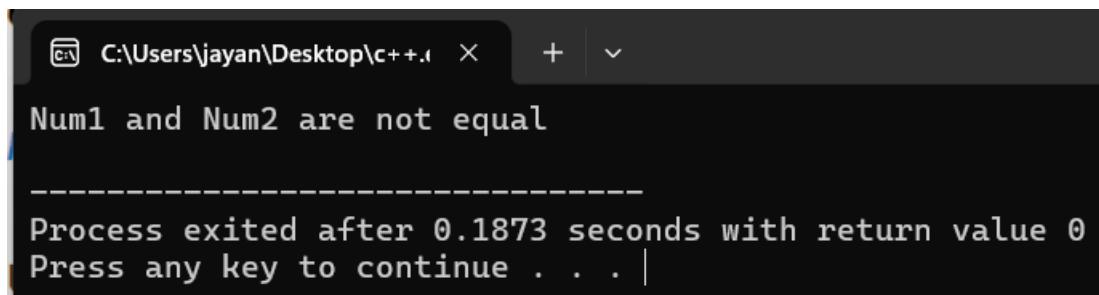

Syntax:

```
if(condition){  
    //body of if statement  
}  
  
else{  
    Body of else statement  
}
```

```
c++.cpp  
1 #include<iostream>  
2 #include<string.h>  
3 using namespace std;  
4  
5 //main function  
6 main() {  
7     int num1=10, num2=20;  
8     if(num1==num2){  
9         cout<<"Num1 and Num2 are equal"<<endl;  
10    }  
11    else{  
12        cout<<"Num1 and Num2 are not equal"<<endl;  
13    }  
14 }
```

Output:

```
C:\Users\jayan\Desktop\c++.i  X + | ^

Num1 and Num2 are not equal
-----
Process exited after 0.1873 seconds with return value 0
Press any key to continue . . . |
```

If/else ladder:

It is used to performed multiple cases for different conditions. In this statement there is one if condition and multiple else if conditions and one else block.

Syntax:

```
if(condition){
    //body of if statement
}

else if(condition){
    //body of else if statement
}

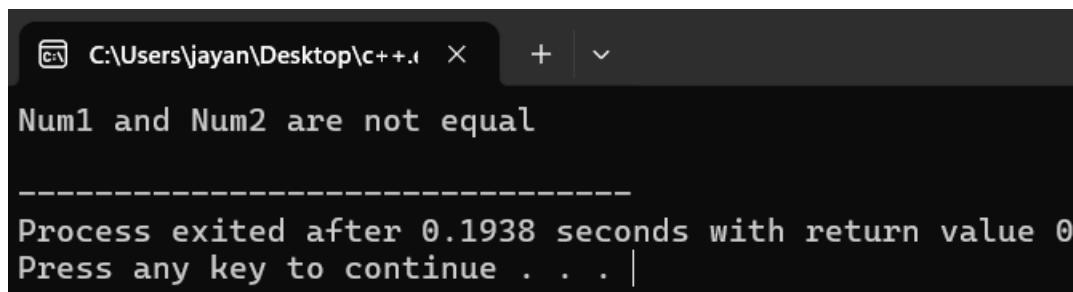

else if(condition){
    //body of else if statement
}

else{
    //body of else statement
}
```

```
#include<iostream>
#include<string.h>
using namespace std;

//main function
main() {
    int num1=10,num2=20;
    if(num1==num2){
        cout<<"Num1 and Num2 are equal"<<endl;
    }
    else if(num1!=num2){
        cout<<"Num1 and Num2 are not equal"<<endl;
    }
    else{
        cout<<"This number is not valid"<<endl;
    }
}
```

Output:

```
C:\Users\jayan\Desktop\c++.i  X  +  ▾
Num1 and Num2 are not equal
-----
Process exited after 0.1938 seconds with return value 0
Press any key to continue . . . |
```

Nested if:

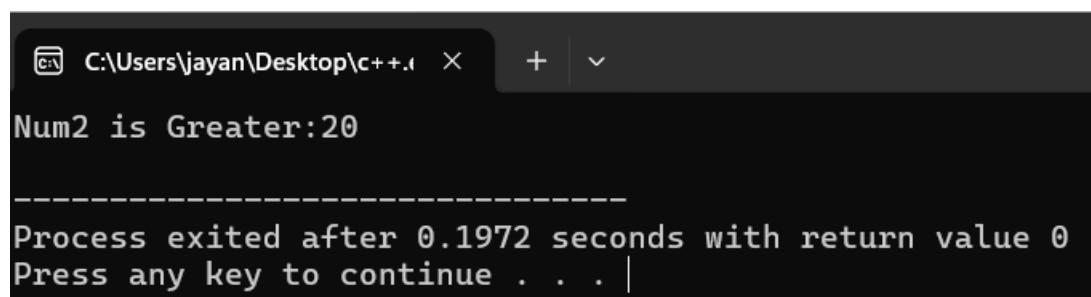

Whenever if statement contain itself another if statement is called Nested-if statement.

Syntax:

```
if(condition){  
    if(condition){  
        //body of 2nd if statement  
    }  
    else{  
        //body of else statement  
    }  
    //body of 1st statement  
}  
else{  
    //body of else statement  
}
```

```
#include<iostream>
#include<string.h>
using namespace std;
main() {
    int num1=10, num2=20, num3=5;
    if(num1>num2){
        if(num1>num3){
            cout<<"Num1 is Greater:"<<num1<<endl;
        }
        else{
            cout<<"Num3 is Greater:"<<num3<<endl;
        }
    }
    else{
        if(num2>num3){
            cout<<"Num2 is Greater:"<<num2<<endl;
        }
        else{
            cout<<"Num3 is Greater:"<<num3<<endl;
        }
    }
}
```

Output:

```
C:\Users\jayan\Desktop\c++.i X + 
Num2 is Greater:20
-----
Process exited after 0.1972 seconds with return value 0
Press any key to continue . . . |
```

Switch Statement

A switch statement allows a variable to be tested for equality against a list of values. Each value is called a case, and the variable being switched on is checked for each switch case.

Rules:

- (i) You can have any number of case statements within a switch. Each case is followed by the value of compared to and a colon.
- (ii) The constant-expression of a case must be the same datatype as the variable in the switch, and it must be a constant or a literal.
- (iii) When the variable being switch on is equal to case, the statements following that case will execute until a break statement is reached.
- (iv) When a break statement is reached, the switch terminates, and the flow of control jump to the next line following the switch statement.
- (v) Not every case needs to contain a break. If no break appears, the flow of control will fall through to subsequent cases until a break is reached.
- (vi) A switch statement can have an optional default case, which must appear at the end of the switch. The default case can be used for performing a task when none of the case is true. No break is needed in the default case.

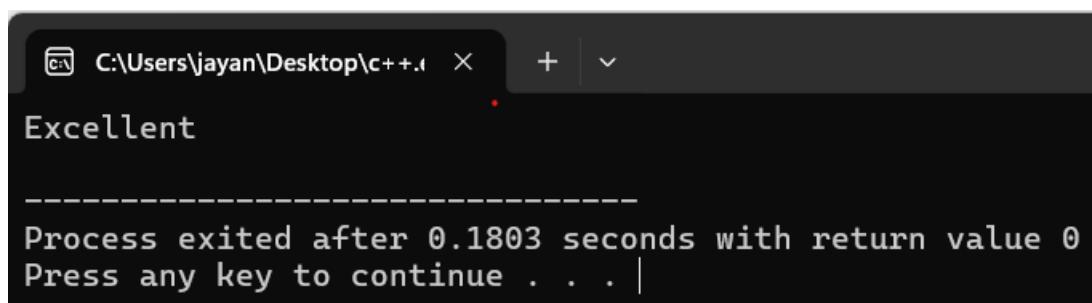

Syntax:

```
switch(expression){  
    case constant_expression:  
        statements  
        break;  
    case constant_expression:  
        statements  
        break;  
    default:  
        statements
```

```
        break;  
    }  
  
}
```

```
#include<iostream>  
using namespace std;  
main() {  
    char grade='A';  
    switch(grade){  
        case 'A':  
            cout<<"Excellent" << endl;  
            break;  
        case 'B':  
            cout<<"Very Good" << endl;  
            break;  
        case 'C':  
            cout<<"Good" << endl;  
            break;  
        default:  
            cout<<"Please Enter Valid Grade" << endl;  
    }  
}
```

Output:

The screenshot shows a terminal window with the following text output:

```
C:\Users\jayan\Desktop\c++.i  X +   
Excellent  
-----  
Process exited after 0.1803 seconds with return value 0  
Press any key to continue . . . |
```

Loops (Control Statement)

A loop executes the sequence of statements many times until the stated condition becomes false. A loop consists two parts, a body of a loop and a control statement. The control statement is a combination of some conditions that direct the body of the loop execute until the specified condition becomes false. The purpose of the loop is to repeat the same code a number of times.

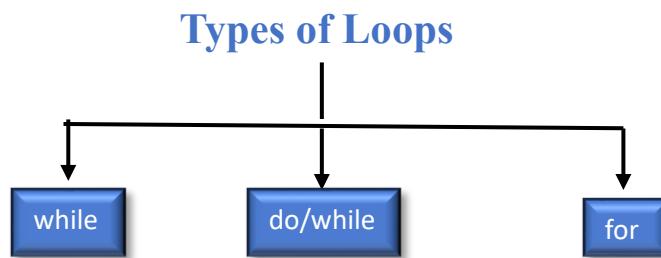

Entry Controlled loop:

In an Entry controlled loop, a condition is checked before executing the body of a loop. It is also called as pre-checking loop.

Exit Controlled loop:

In an Exit Controlled loop, a condition is checked after executing the body of a loop. It is also called a post-checking loop.

The control conditions must be well defined and specified otherwise the loop will execute an infinite number of times. The loop doesn't stop executing and process the statements number of times is called as an infinite loop. An infinite loop is also called as an “Endless loop”.

While:

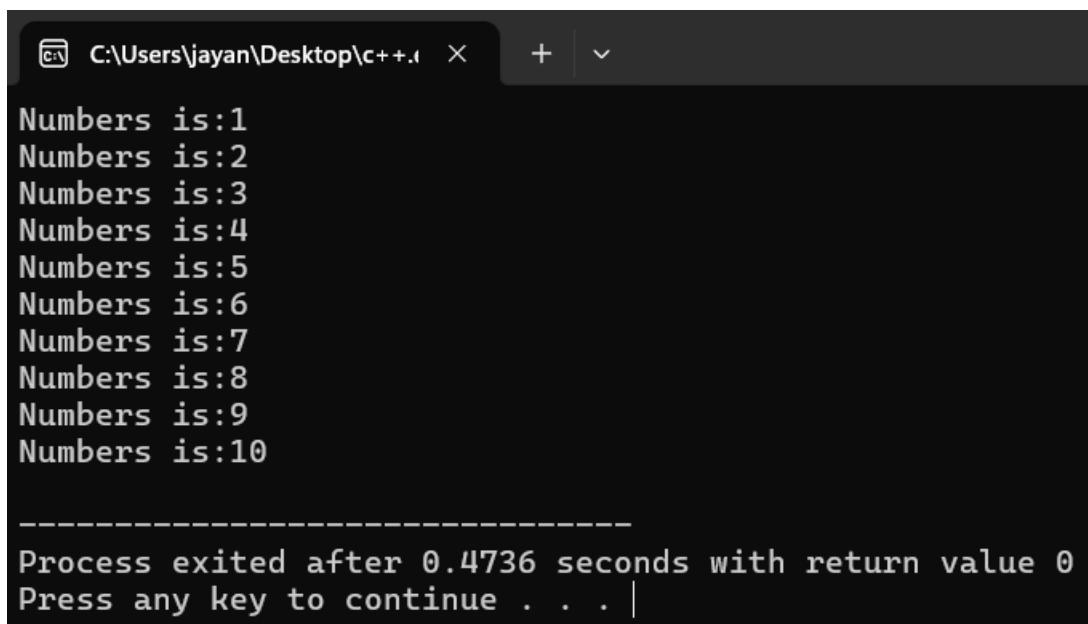

A while loop is the most straight forward looping structure.

Syntax:

```
while(condition){  
//body of while }
```

```
#include<iostream>  
using namespace std;  
main() {  
    int a=1;  
    while(a<=10){  
        cout<<"Numbers is:"<<a<<endl;  
        a++;|  
    }  
}
```

Output:

```
C:\Users\jayan\Desktop\c++.i + v

Numbers is:1
Numbers is:2
Numbers is:3
Numbers is:4
Numbers is:5
Numbers is:6
Numbers is:7
Numbers is:8
Numbers is:9
Numbers is:10

-----
Process exited after 0.4736 seconds with return value 0
Press any key to continue . . . |
```

Do-While:

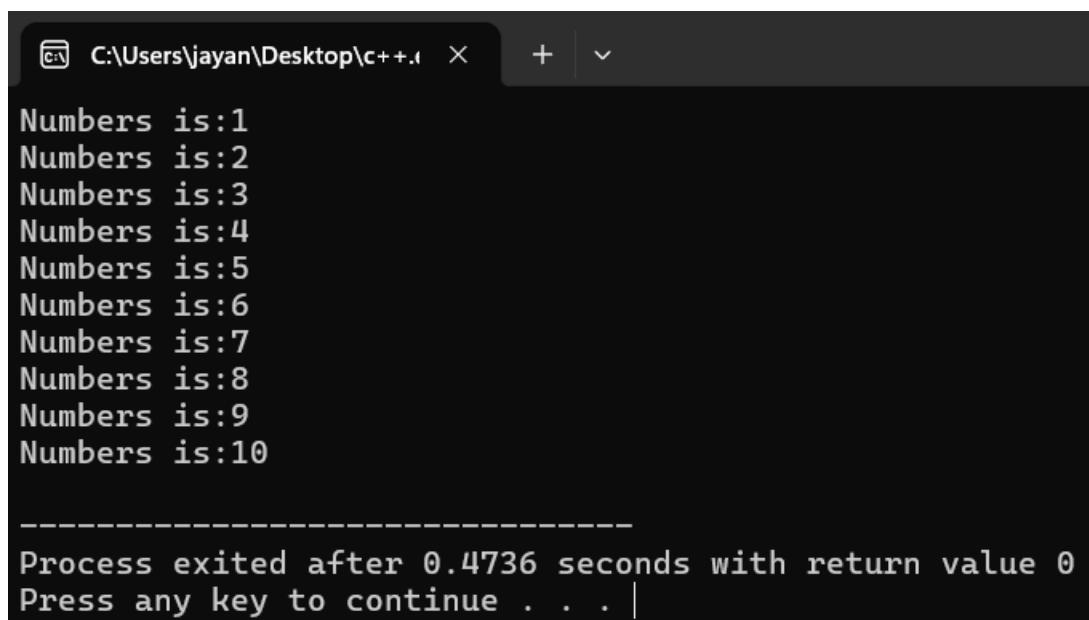

A do while loop in C++ is similar to the while loop except that the condition is always executed after the body of a loop. It is also called an exit controlled loop.

Syntax:

```
do{
    //body of do
}while(condition);
```

```
#include<iostream>
using namespace std;
main() {
    int a=1;
    do{
        cout<<"Numbers is:"<<a<<endl;
        a++;
    }while(a<=10);
}
```

Output:

```
C:\Users\jayan\Desktop\c++.i  X + ▾
Numbers is:1
Numbers is:2
Numbers is:3
Numbers is:4
Numbers is:5
Numbers is:6
Numbers is:7
Numbers is:8
Numbers is:9
Numbers is:10
-----
Process exited after 0.4736 seconds with return value 0
Press any key to continue . . . |
```

For:

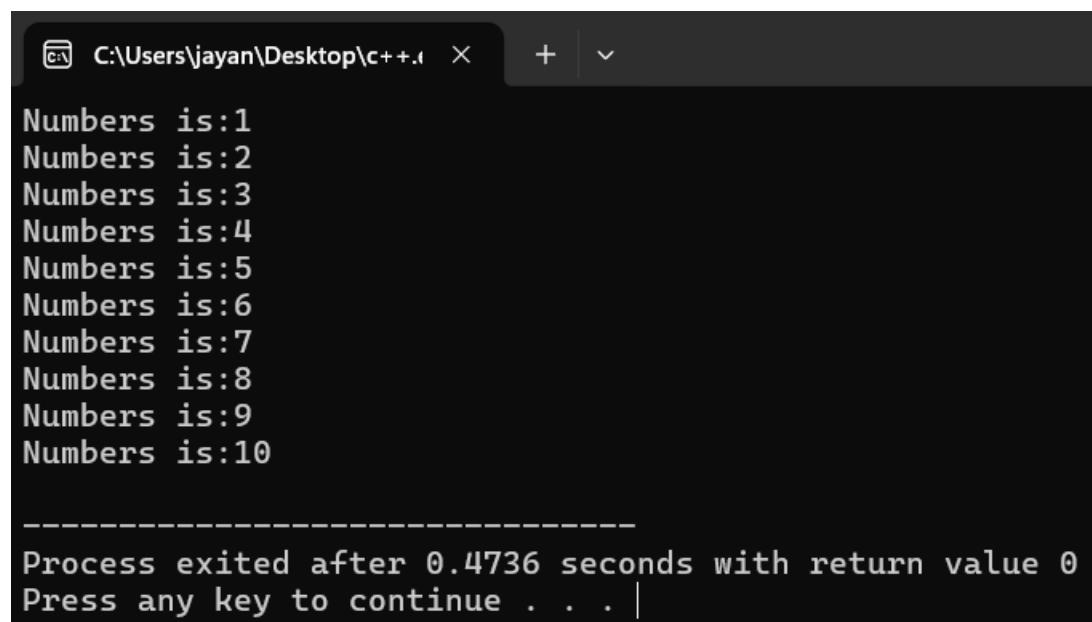

A for loop is a more efficient loop structure in C++ programming. The general structure is offer loop syntax:

Syntax

```
for(initial value;condition;operator(++,--)){  
    //body of for  
}
```

```
#include<iostream>  
using namespace std;  
main() {  
    for(int num=1;num<=10;num++){  
        cout<<"Numbers is:"<<num<<endl;  
    }  
}
```

Output:

```
C:\Users\jayan\Desktop\c++.i  X + | v  
  
Numbers is:1  
Numbers is:2  
Numbers is:3  
Numbers is:4  
Numbers is:5  
Numbers is:6  
Numbers is:7  
Numbers is:8  
Numbers is:9  
Numbers is:10  
  
-----  
Process exited after 0.4736 seconds with return value 0  
Press any key to continue . . . |
```

Nested for loop:

For loops can also be nested where there is an outer loop and an inner loop. For each iteration of the outer loop, the inner loop repeats its entire cycle.

Syntax

```
for(initial value; condition; operator(++,--)){  
    For (initial value; condition; operator(++,--)){  
        //body of second loop  
    }  
    //body of first loop  
}
```

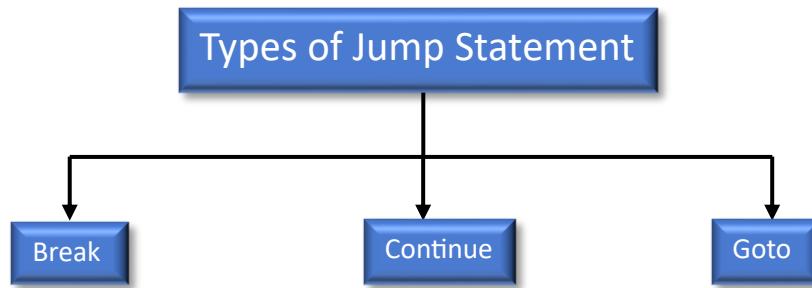

```
#include<iostream>  
using namespace std;  
main() {  
    int table_no;  
    cout<<"Enter Number:";  
    cin>>table_no;  
    for(int num1=table_no;num1<=table_no;num1++){  
        for(int num2=1;num2<=10;num2++){  
            cout<<num1<<"*"<<num2<<"="<<num1*num2<<endl;  
        }  
    }  
}
```

Output:

```
C:\Users\jayan\Desktop\c++.i + ▾
Enter Number:2
2*1=2
2*2=4
2*3=6
2*4=8
2*5=10
2*6=12
2*7=14
2*8=16
2*9=18
2*10=20
-----
Process exited after 3.284 seconds with return value 0
Press any key to continue . . . |
```

Jumping Statement

The statement are used in C++ for unconditional flow of control throughout the function in a program. They support three types of jump statement.

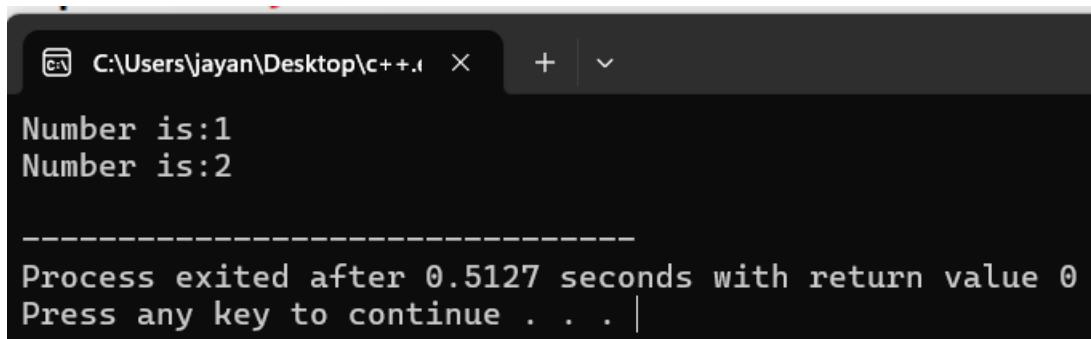

Break:

- (i)The loop control statement is used to terminate the loop. As soon as the break statement is encountered from within a loop, the loop iterations stops there and control returns from the loop immediately to the first statement after the loop.
- (ii)Basically break statements are used in the situations when we are not sure about the actual number of iterations for the loop or we want to terminate the loop based on some condition.

```
#include<iostream>
using namespace std;
main() {
    for(int i=1;i<=5;i++){
        if(i==3){
            break;
        }
        cout<<"Number is:"<<i<<endl;
    }
}
```

Output:

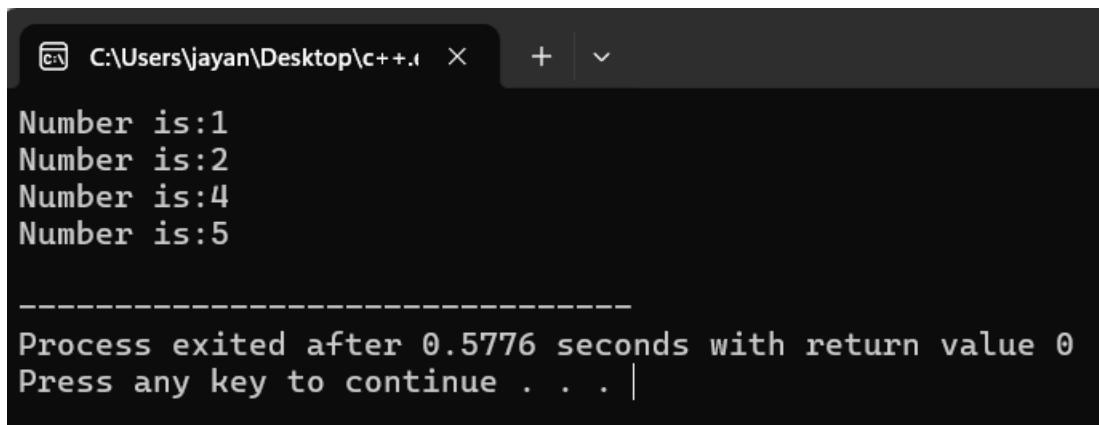

```
C:\Users\jayan\Desktop\c++.i  X + | ~
Number is:1
Number is:2
-----
Process exited after 0.5127 seconds with return value 0
Press any key to continue . . . |
```

Continue:

The continue statement is opposite to that break statement, instead of terminating the loop, it forces to execute the next iteration of the loop.

```
#include<iostream>
using namespace std;
main() {
    for(int i=1;i<=5;i++){
        if(i==3){
            continue;
        }
        cout<<"Number is:"<<i<<endl;
    }
}
```

Output:

```
C:\Users\jayan\Desktop\c++.i + ▾
```

```
Number is:1
Number is:2
Number is:4
Number is:5

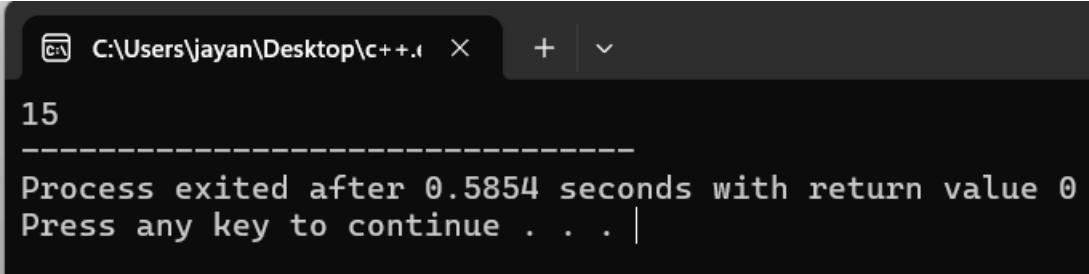

-----
Process exited after 0.5776 seconds with return value 0
Press any key to continue . . . |
```

Goto:

The goto statement in C++ also referred to as unconditional jump statement can be used to jump from one point to another point within a function.

```
#include<iostream>
using namespace std;
main() {
    int i,sum=0;
    for(i=0;i<=10;i++){
        sum+=i;
        if(i==5){
            goto addition;
        }
    }
    addition:
    cout<<sum;
}
```

Output:

A screenshot of a terminal window titled "C:\Users\jayan\Desktop\c++.i". The window contains the following text:
15

Process exited after 0.5854 seconds with return value 0
Press any key to continue . . . |

Pointers

The pointer in C++, is a variable that stores address of another variable. A pointer can also be used to refer to another pointer function. A pointer can be increment and decrement, point to the next/previous memory location. The purpose of pointer is to save memory space and achieve faster execution time.

Note: & : Address , * : Declaration

Declaring a pointer:

(i) Pointers declared before they can be used in your program. Pointers can be named anything you want as long as they obey C++ naming rules.

Syntax:

```
data_type *pointer_variable_name;
```

(ii) The asterisk (*) which is indirection operator, declares a pointer.

Initialize a pointer:

(i) If pointers in C++ programming are not uninitialized and used in the program, the result are unpredictable and potentially disastrous.

(ii) We use the ampersand (&) operator, placed before the name of a variable whose address we need. Pointer initialization is done with the following syntax.

```
pointer=&variable;
```

Advantages:

(i) Pointers are useful for accessing memory location.

(ii) Pointers provide an efficient way for accessing the elements of an array structure.

(iii) Pointers are used for dynamic memory allocation as well as deallocation.

(iv) Pointers are used to form complex data structures such as linked list, graph, tree etc.

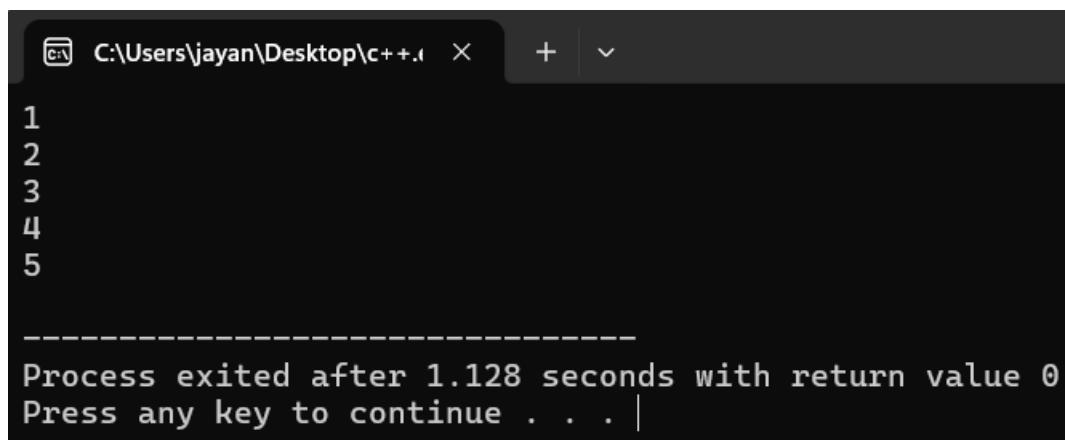

Disadvantages:

(i) Pointers are a little complex to understand.

- (ii) Pointers can lead to various errors such as segmentation faults or can access a memory location which is not required at all.
- (iii) If an incorrect value is provided to a pointer, it may cause memory corruption.
- (iv) Programmers find it very difficult to work with the pointers; therefore it is programmer's responsibility to manipulate a pointer carefully.

```
#include<iostream>
using namespace std;
main() {
    int i,a[5]={1,2,3,4,5};
    int *p=a;
    for(i=0;i<5;i++){
        cout<<*p<<endl;
        p++;
    }
}
```

Output:

```
C:\Users\jayan\Desktop\c++.i + ▾
```

```
1
2
3
4
5
-----
Process exited after 1.128 seconds with return value 0
Press any key to continue . . . |
```

Structure

- (i) In C++, there are cases where we need to store multiple attributes of an entity. It is not necessary that an entity has all the information of one type only. It can have different attributes of different data types.
- (ii) Construct individual arrays for storing names, roll numbers, and marks.
- (iii) Use a special data structure to store the collection of different data types.
- (iv) Structure in C++ is a user-defined data type that enables us to store the collection of different datatypes.
- (v) struct keyword are used for create structure

Syntax:

```
struct structure_name {  
    datatype member1;  
    datatype member2;  
    datatype member n;  
};
```

Declaration of Structure:

- (i) We can declare a variable for the structure so that we can access the member of the structure easily. There are two ways to declare struct variable.
- (ii) By struct keyword within main() function.
- (iii) By declaring a variable at the time of defining the structure.
- (iv) The variable e1 and e2 can be used to access the values stored in the structure.
- (v) Another way to declare variable at the time of defining the structure:

```
struct employee {  
    int id;  
    char name[50];  
    float salary;
```

```
}e1,e2;
```

```
#include<iostream>
using namespace std;
//Structure
struct student{
    int roll_no;
    char name[10];
    float percentage;
}s1;
//Main function
main() {
    cout<<"Enter the details of students:"<<endl;
    cout<<"Enter Name:";
    cin>>s1.name;
    cout<<endl<<"Enter Roll No:";
    cin>>s1.roll_no;
    cout<<endl<<"Enter Percentage:";
    cin>>s1.percentage;
    cout<<"Name is:"<<s1.name<<endl;
    cout<<"Roll No is:"<<s1.roll_no<<endl;
    cout<<"Percentage:"<<s1.percentage<<endl;
}
```

Output:

```
C:\Users\jayan\Desktop\c++.i + ▾
Enter the details of students:
Enter Name:Ram

Enter Roll No:123

Enter Percentage:100
Name is:Ram
Roll No is:123
Percentage:100

-----
Process exited after 7.423 seconds with return value 0
Press any key to continue . . . |
```

Union

(i)A union is a special datatype available in C++ that allows to store different data types in the same memory location. You can define a union with many members, but only one member can contain a value at any given time. Unions provide an efficient way of using the same memory location for multiple purpose.

(ii)The union statement defines a new datatype with more than one member for your program:

Syntax:

```
Union union_name{
```

```
    Member definition;
```

```
    } variables;
```

(iii)A variable of datatype can store an integer, a floating point numbers, or a string of characters. It means a single variable. Same memory location, can be used to store multiple types of data. You can use any built-in or user defined datatypes inside a union based on your requirements.

(iv)The memory occupied by a union will be large enough to hold the largest member of the union.

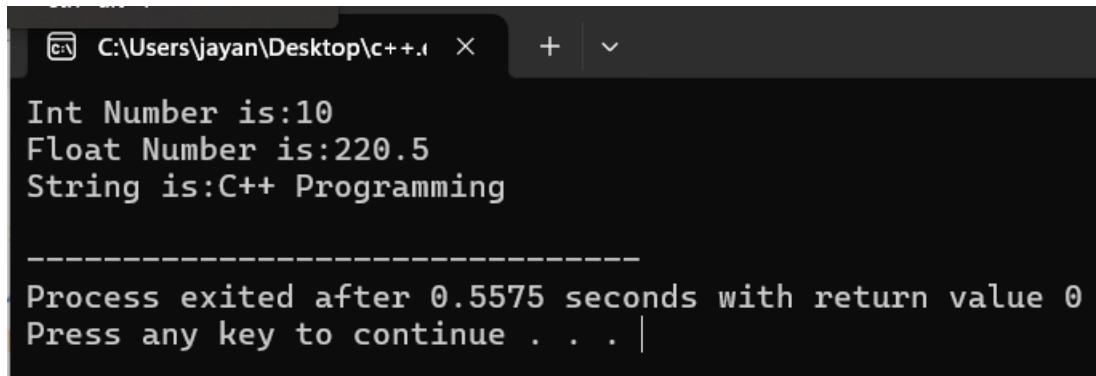

Accessing Union Members

To access any member of a union, we use the member access operator(.). The member access operator is coded as a period between the union variable name and the union member that we wish to access. You would use the keyword union to define variables of union type.

```
#include<iostream>
#include<string.h>
using namespace std;
//Structure
union Data{
    int i;
    float f;
    char str[20];
};
//Main function
main() {
    union Data data;
    data.i=10;
    cout<<"Int Number is:"<<data.i<<endl;

    data.f=220.5;
    cout<<"Float Number is:"<<data.f<<endl;
|
    strcpy(data.str,"C++ Programming");
    cout<<"String is:"<<data.str<<endl;
}
```

Output:

The screenshot shows a terminal window with the following output:

```
C:\Users\jayan\Desktop\c++.i > 
Int Number is:10
Float Number is:220.5
String is:C++ Programming
-----
Process exited after 0.5575 seconds with return value 0
Press any key to continue . . . |
```

Storage Classes

Storage classes are used to determine the lifetime, visibility, memory location, and initial value of a variable. They are four types of storage classes in C++.

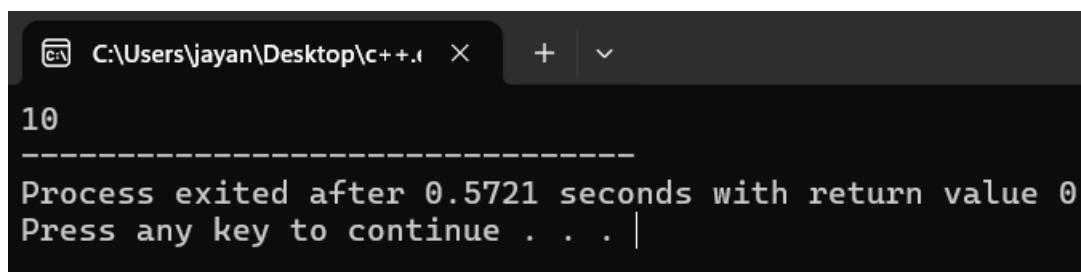

Storage Classes	Storage Place	Default Value	Scope	Lifetime
Auto	Ram	Garbage value	Local	Within Function
Extern	Ram	Zero	Global	Till the end of the program maybe decrease anywhere in the program.
Static	Ram	Zero	Local	Till end of the main program, retains value between multiple function call.
Register	Register	Garbage Value	Local	Within the function

Automatic(auto):

- (i) Automatic variable are allocated memory automatically at runtime.
- (ii) Visibility of the auto variables is limited to the block in which they are defined.
- (iii) Scope of the auto variable is limited to the block in which they are defined.
- (iv) It is initialized to the garbage value by default.
- (v) The memory assigned to automatic variables gets freed upon exiting from the block.
- (vi) Every local variable is automatic in C++ by default.

```
#include<iostream>
#include<string.h>
using namespace std;
main(){
    auto int a=10;
    cout<<a;
}
```

Output:

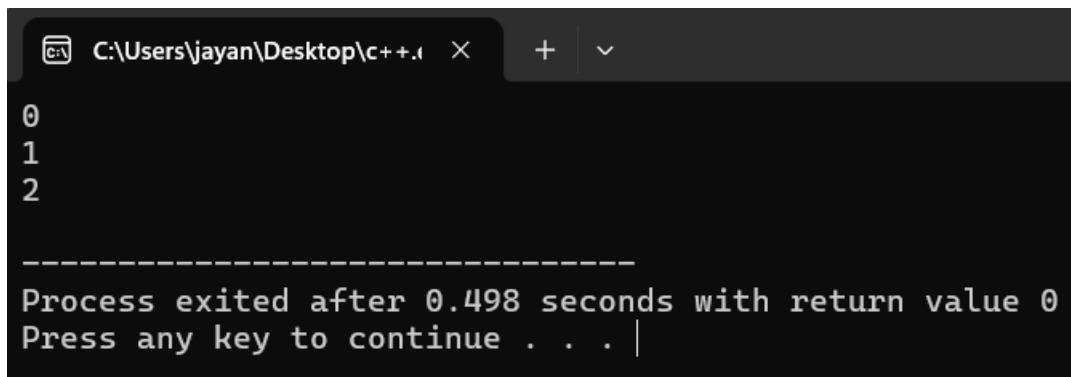

```
C:\Users\jayan\Desktop\c++.i  X + | v
10
-----
Process exited after 0.5721 seconds with return value 0
Press any key to continue . . . |
```

Static:

- (i)The variables defined as static specifier can hold their values between the multiple function calls.
- (ii)Static local variable are visible only to the function or the block in which they are defined.
- (iii)A same static variable can be declared many times but can be assigned at only one time.
- (iv)Default initial value of the static integral variable is 0 otherwise null.
- (v)The visibility of the static global variable is limited to the life in which it has declared.

```
#include<iostream>
#include<string.h>
using namespace std;
int fun_static(){
    static int num=0;
    cout<<num<<endl;
    num++;
    return 0;
}
main(){
    for(int i=1;i<4;i++){
        fun_static();
    }
}
```

Output:

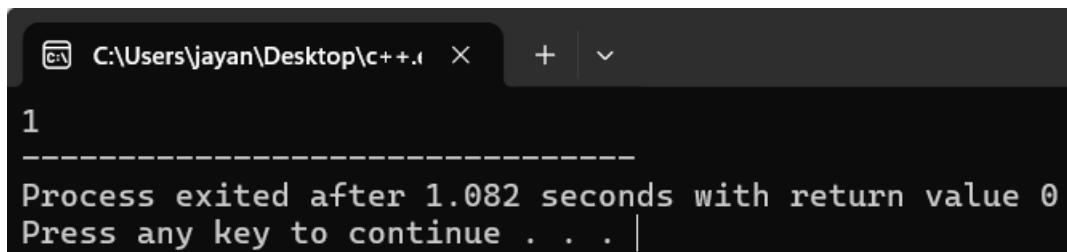

```
0
1
2
-----
Process exited after 0.498 seconds with return value 0
Press any key to continue . . . |
```

Register:

- (i) The variable defines as the register is allocated the memory into the CPU, registers depending upon size of the memory remaining in the CPU.
- (ii) We can not use & operator for the register variable.
- (iii) The access time of the register variable is faster than the automatic variables.
- (iv) The initial default value of the register local variable is 0.
- (v) We can store pointers into the register, register can store the address of a variable.
- (vi) Static variables cannot stored into the register since we can not use more than one storage specifier for the same variable.

```
#include<iostream>
#include<string.h>
using namespace std;
main(){
register int a;
cout<<a;
}
```

Output:

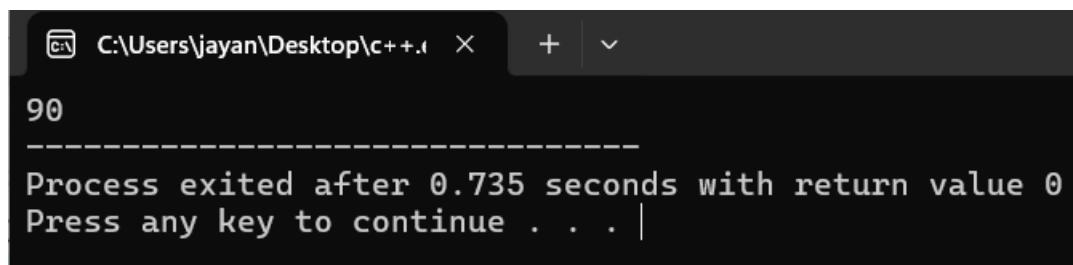

```
C:\Users\jayan\Desktop\c++.i  X + | v
1
-----
Process exited after 1.082 seconds with return value 0
Press any key to continue . . . |
```

External:

- (i)The external storage class is used to tell the compiler that the variable that the variable defined as extern is declared with an external linkage else where in the program.
- (ii)The variable declared as extern are not allocated any memory. It is only declaration and intended to specify that the variable is declared elsewhere in the program.
- (iii)The default value of external integral type of 0 otherwise null.
- (iv)We cannot initialize the external variable within any block or method.
- (v) An external variable can be declared many times but can be initialized at once only.

```
#include<iostream>
using namespace std;
extern int a=90;
main(){
    cout<<a;
}
```

Output:

A screenshot of a terminal window titled "C:\Users\jayan\Desktop\c++.i". The window displays the following text:
90

Process exited after 0.735 seconds with return value 0
Press any key to continue . . . |

Arrays and its types

(i) Array is a kind of data structure that can store a fixed-size sequential collection of elements of the same type. An array is used to store a collection of data, but it is often more useful to think of an array as a collection of variables of the same.

Declaration

To declare an array in C++, a programmer specifies the type of the elements and number of elements required by an array.

```
Datatype array_name[array_size];
```

This is called single dimensional array.

The array size must be an integer constant greater than zero and type can be any valid C++ datatype.

```
Double balance[10];
```

Array initialization:

The simplest way to initialize an array is by using the index of each element. We can initialize each element of the array by using the index.

```
Marks[0]=80;
```

```
Marks[1]=60;
```

(i) You can initialize an array in C++ either one by one or using a single statement.

(ii) `double balance[5]={1000.0,2.3,5.9,6.3,200.0};`

(iii) The number of values between braces {} cannot be larger than the number of elements that we declare for the array between square brackets [].

(iv) If you omit the size of the array, an array just big enough to hold the initialization is created.

(v) Assign a single element of the array

```
Balance[4]=50.0
```

(vi)The above statement assigns the 5th element in the array with a value of 50.0.All arrays have 0 as the index of their first element which is also called the base index and the last index of an array will be total size of the array.

Accessing an array element:

(i)An element is accessed by indexing the array name.This is done by placing the index of the element within the square brackets after the name of the array.

Double salary=balance[9];

(ii)The above statement will take the 10th element from the array and assign the value to salary variable.

.

```
#include<iostream>
using namespace std;
//main function
main(){
    int i=0,marks[5]={20,30,40,50,60};
    cout<<"Array is:"<<endl;
    for(i=0;i<5;i++){
        cout<<marks[i]<<endl;
    }
}
```

Output:

```
C:\Users\jayan\Desktop\c++.i + ▾
Array is:
20
30
40
50
60
-----
Process exited after 0.5214 seconds with return value 0
Press any key to continue . . . |
```

Two Dimensional Arrays:

(i)The simplest form of multidimensional array is the two dimensional arrays. A two dimensional arrays is, in essence a list of one-dimensional arrays. To declare a two dimensional integer array of size[x][y], you would write something.

(ii) datatype arrayName[x][y];

(iii)Where type can be any valid C++ datatype and arrayName will be a valid C++ identifier. A two dimensional array can be considered as a table which will have x number of rows and y number of columns.

	Column1	Column1	Column2	Column3
Row0	a[0][0]	a[0][1]	a[0][2]	a[0][3]
Row1	a[1][0]	a[1][1]	a[1][2]	a[1][3]
Row2	a[2][0]	a[2][1]	a[2][2]	a[2][3]

Initializing 2D Array

Multidimensional arrays many be initialized by specifying bracket values for each row.Following is an array with 3 rows and each rows has 4 columns.

Int a[3][4]={ {0,1,2,3}, {4,5,6,7}, {8,9,10,11} };

Accessing a 2D Array

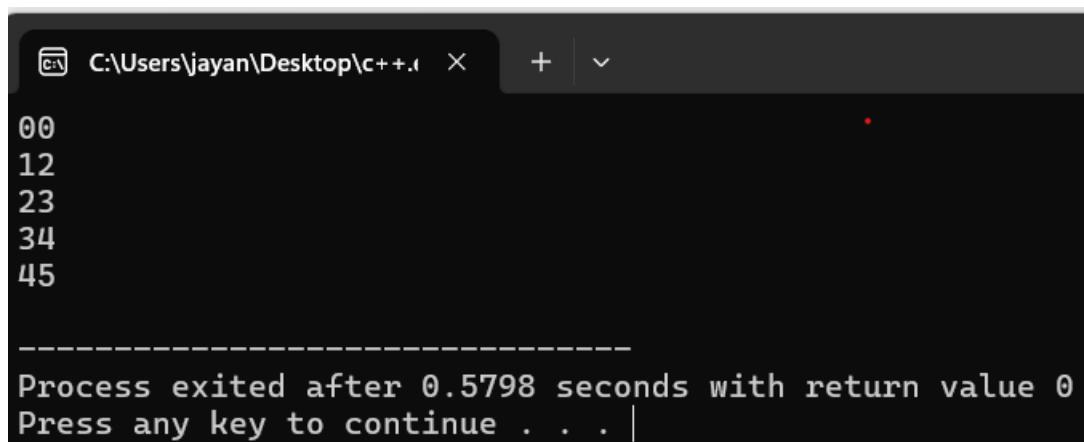

An element in a two dimensional array is accessed by using the subscript, row index and column index of the array.

int val=a[2][3];

The above statement will be take the 4th element from the 3rd row of the array.

```
#include<iostream>
using namespace std;
//main function
main(){
    int a[5][2]={{0,0},{1,2},{2,3},{3,4},{4,5}};
    for(int i=0;i<5;i++){
        for(int j=0;j<2;j++){
            cout<<a[i][j];
        }
        cout<<endl;
    }
}
```

Output:

```
C:\Users\jayan\Desktop\c++.i  X  +  ▾
00
12
23
34
45
-----
Process exited after 0.5798 seconds with return value 0
Press any key to continue . . . |
```

3D Arrays

Total numbers of elements that can be stored in a multidimensional array can be calculated by multiplying the size of all the dimensional.

Declare 3D Array:

- (i)Specify datatype, arrayName, block size, row size and column size.
- (ii)Each subscript can be written within its own separate pair of brackets.

```
int arr[2][2][2];
```

Accessing 3D array:

Accessing elements in three dimensional arrays is also similar to that of two dimensional arrays. The difference is we have to use three loops instead of two loops for one additional dimension in three dimensional arrays.

```
#include<iostream>
using namespace std;
//main function
main(){
    int arr[3][3][3]={
        {
            {11,12,13},
            {14,15,16},
            {16,17,18},
        },
        {
            {1,1,1},
            {1,1,1},
            {1,1,1},
        },
        {
            {1,2,3},
            {1,2,3},
            {1,2,3},
        }
    };

    for(int i=0;i<3;i++){
        for(int j=0;j<3;j++){
            for(int k=0;k<3;k++){

```

```
23 for(int i=0;i<3;i++){
24     for(int j=0;j<3;j++){
25         for(int k=0;k<3;k++){
26             cout<<arr[i][j][k]<< " ";
27         }
28         cout<<endl;
29     }
30     cout<<endl;
31 }
32 }
```

Output:

```
C:\Users\jayan\Desktop\c++.i + ^

11 12 13
14 15 16
16 17 18

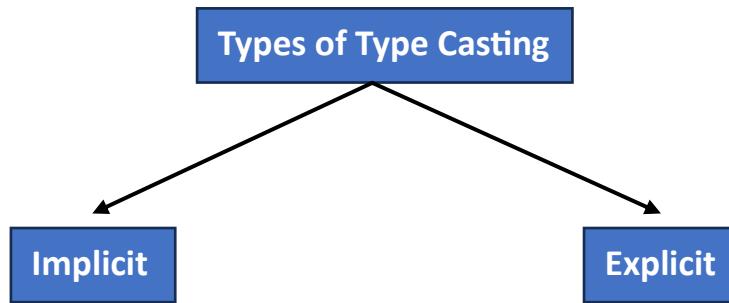

1 1 1
1 1 1
1 1 1

1 2 3
1 2 3
1 2 3

-----
Process exited after 0.9506 seconds with return value 0
Press any key to continue . . . |
```

Type Casting

Type casting is converting one data type into another one data type. It is also known as data conversion or type conversion.

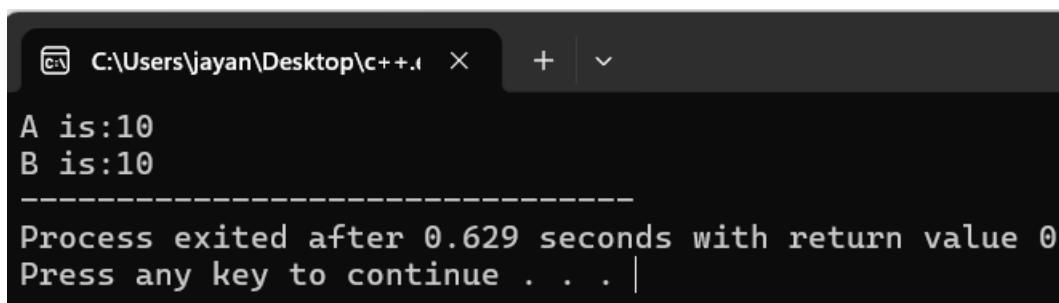

Implicit:

Implicit type casting means conversion of datatypes without losing its original meaning. This type of typecasting is essential when you want to change datatype without changing the significance of the value stored inside the variable.

```
#include<iostream>
using namespace std;
//main function
main(){
    short a=10;
    int b;
    b=a;
    cout<<"A is:"<<a<<endl;
    cout<<"B is:"<<b;
}
```

Output:

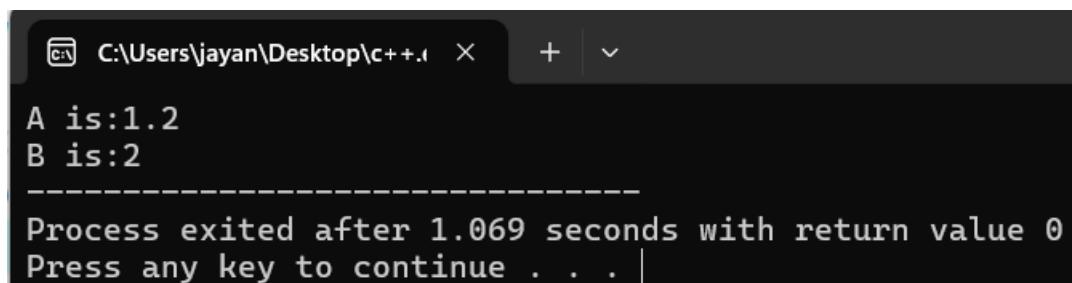

```
C:\Users\jayan\Desktop\c++.i + | v
A is:10
B is:10
-----
Process exited after 0.629 seconds with return value 0
Press any key to continue . . . |
```

Explicit:

In Explicit type casting, the data type converted automatically. There are some scenarios in which we may have to force type conversion.

```
#include<iostream>
using namespace std;
//main function
main(){
    float a=1.2;
    int b=int(a)+1;
    cout<<"A is:"<<a<<endl;
    cout<<"B is:"<<b;
}
```

Output:

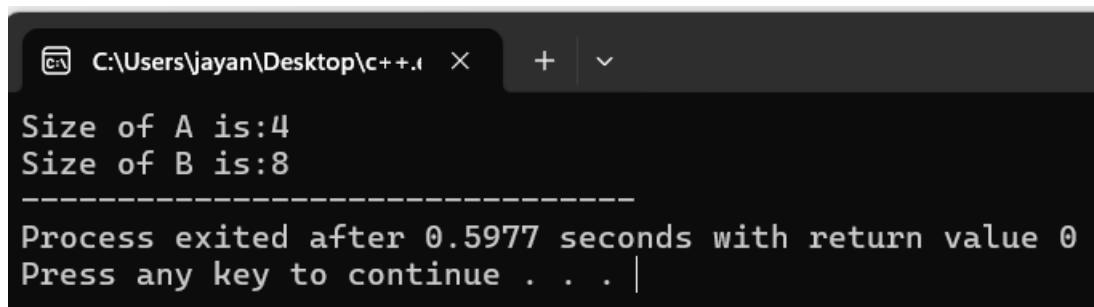

```
C:\Users\jayan\Desktop\c++.i + | v
A is:1.2
B is:2
-----
Process exited after 1.069 seconds with return value 0
Press any key to continue . . . |
```

Size-of operator

The operator returns the size of its operand, in bytes. The size of operator always proceeds its operand. The operand is an expression, or it may be cast.

```
#include<iostream>
using namespace std;
//main function
main(){
    int a;
    double b;
    cout<<"Size of A is:"<<sizeof(a)<<endl;
    cout<<"Size of B is:"<<sizeof(b);
}
```

Output:

```
C:\Users\jayan\Desktop\c++.i + | v
Size of A is:4
Size of B is:8
-----
Process exited after 0.5977 seconds with return value 0

Pre-Processor Directives

The preprocessor in C++ is used for processing the code before it is compiled by the compiler. It does many tasks such as including files, conditional compilation, using macros, etc. The preprocessor also allows the developers to select which portions of code should be included or excluded.

In C++, the preprocessor directives are special commands that are used to instruct the preprocessor. It begins with a '#' symbol and tells the preprocessor to modify source code before compilation.

Directives	Purpose
#include	Links a header file in the source code.
#define	Creates a symbolic or macro constant.
#undef	Deletes a macro that has already been defined.
#ifdef/#ifndef	Compilation that is conditional on the presence or absence of a macro.
#if/#else/#endif	Compilation that is conditional based on some expression.
#error	Halts the compilation process and produces an error notice.
#warning	During compilation, a warning notice is shown.
#pragma	Provide the compiler specific instruction.

#include:

The #include preprocessor directive is used to include the contents of one file into the current one, use the #include directive.

Syntax:

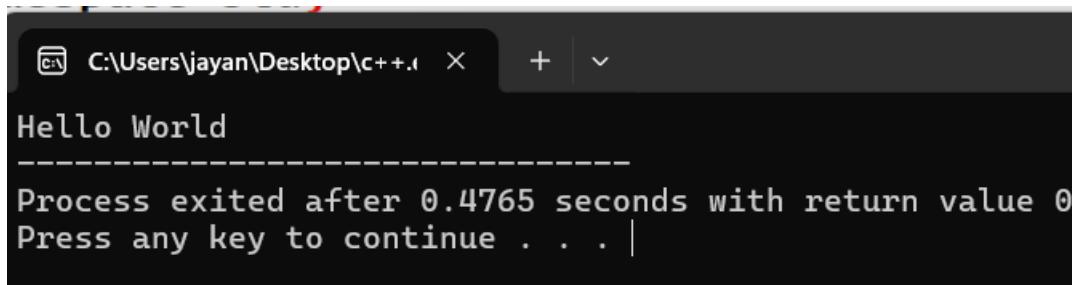

#include<headerFileName>

or

#include"headerFileName"

```
#include<iostream>
using namespace std;
//Main Function
int main(){
    cout<<"Hello World";
    return 0;
}
```

Output:

A screenshot of a terminal window titled 'C:\Users\jayan\Desktop\c++.i'. The window displays the output of a C++ program. The output consists of the text 'Hello World' followed by a dashed line, and then the message 'Process exited after 0.4765 seconds with return value 0'. Below this, there is a prompt 'Press any key to continue . . . |'.

#define:

(i)The #define preprocessor directive is used to define macros. Macro names are symbolic and may be used to represent constant values or short bits of code.

(ii)Using #define preprocessor makes our code more readable and easily maintainable as we can replace numbers and code snippets with a meaningful name.

Syntax:

#define macroName value

```
c++.cpp
1 #include<iostream>
2 #define PI 3.14
3 using namespace std;
4 //Main Function
5 void area(float radius,float height){
6     float total=PI*(radius*radius)*height;
7     cout<<"Area is:"<<total;
8 }
9 int main(){
10     area(20.5,10.2);
11     return 0;
12 }
```

Output:

```
C:\Users\jayan\Desktop\c++.i + 
Area is:13459.8
-----
Process exited after 0.4996 seconds with return value 0
Press any key to continue . . . |
```

OOPs (Object Oriented Programming)

Classes and Objects

Classes:

A class in C++ is the building blocks, that leads to object oriented programming. It is a user-defined data type, which holds its own data members and members functions, which can be accessed by creating an instance of that class.

Syntax:

```
class className{  
    //Access Specifier:  
    //Data Members;  
    //Member Functions()  
};
```

Note: By default access specifier is private in C++.

Object:

An object is an instance of class. When a class is defined no memory is allocated but when it is instantiated (i.e an object is created) memory is allocated.

Declaring Objects:

When a class is defined, only the specification for the object is defined; no memory or storage is allocated. To use the data and access functions defined in the class, you need to create objects.

Accessing data members and member functions

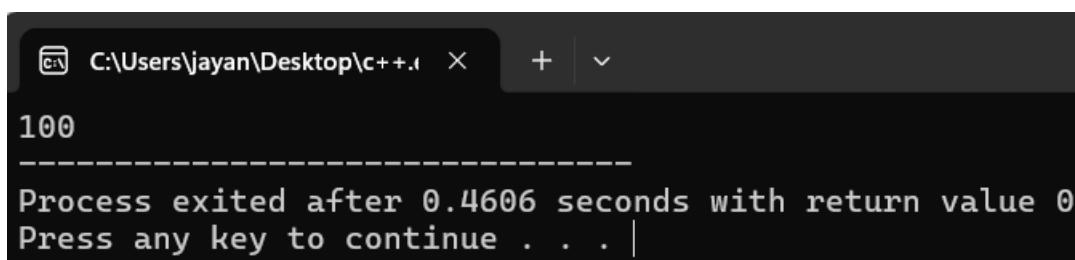

The data members and members functions of class can be accessed using the dot(.) operator with the object.

Syntax:

```
ClassName objectName;
```

```
#include<iostream>
using namespace std;
//Class
class Calculation{
    public:
        int add(){
            int num1=10,num2=90;
            int total=num1+num2;
            cout<<total;
        }
};
//main function
main(){
    //Create object
    Calculation obj;
    //function call
    obj.add();
}
```

Output:

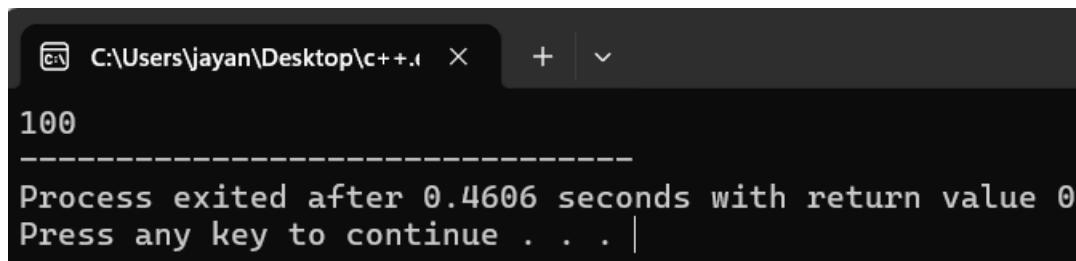

A screenshot of a terminal window titled 'C:\Users\jayan\Desktop\c++.i'. The window displays the output of a C++ program. The output consists of the number '100' followed by a horizontal line and the text 'Process exited after 0.4606 seconds with return value 0'. At the bottom, there is a prompt 'Press any key to continue . . . |'.

Encapsulation

- (i)The wrapping up of data and function into a single unit (called class) is known as Encapsulation.
- (ii)Data and Encapsulation is the most striking feature of a class. The data is not accessible to the outside world, and only those functions which wrapped in the class can access it.
- (iii)These functions provide the interface between the objects data and the program. This insulation of the data from direct access by the program is called hiding or information hiding.

```
#include<iostream>
using namespace std;
//Class
class Calculation{
public:
    int add(){
        int num1=10,num2=90;
        int total=num1+num2;
        cout<<total;
    }
};
//main function
main(){
    //Create object
    Calculation obj;
    //function call
    obj.add();
}
```

Output:

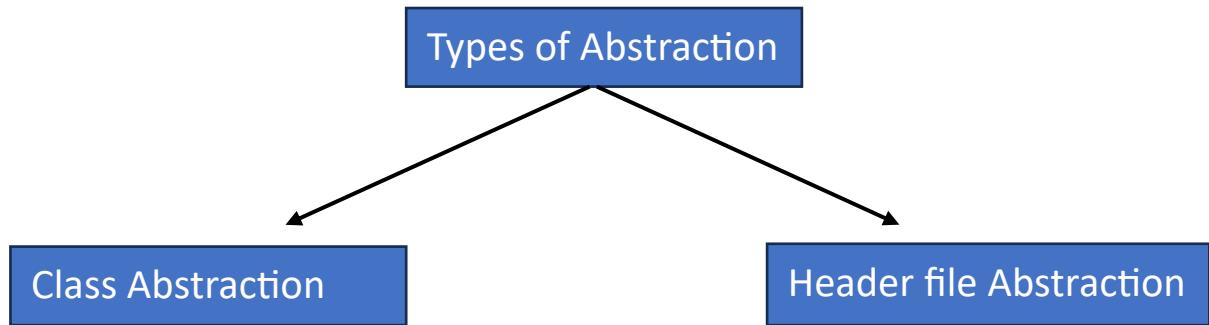

A screenshot of a terminal window titled "C:\Users\jayan\Desktop\c++.i". The window contains the following text:
100

Process exited after 0.4606 seconds with return value 0
Press any key to continue . . . |

Abstraction

Data Abstraction refers to providing only essential information about the data to the outside world, hiding the background details or implementation.

Class Abstraction:

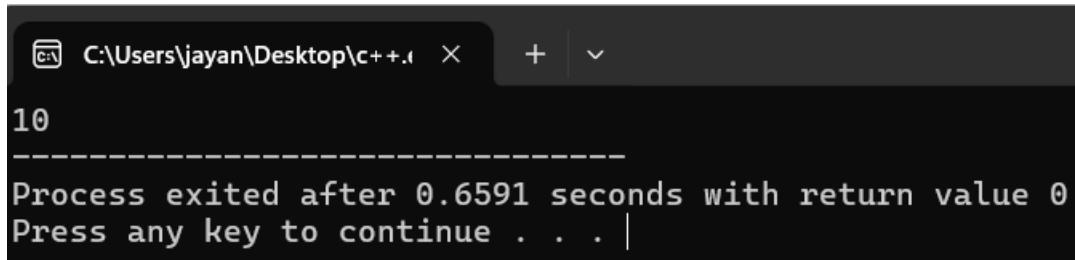

We can implement abstraction in C++ using classes. Class helps us to group data members and members functions using available access specifiers.

Header File Abstraction:

It refers to that header file when functions are hidden in already in the header file without using header files functions cannot access.

```
#include<iostream>
using namespace std;
//Class
class Calculation{
    //data hiding
    private:
        int a;
    public:
        int b(){
            a=10;
            cout<<a;
            return 0;
        }
};
//main function
main(){
    //Create object
    Calculation obj;
    //function call
    obj.b();
}
```

Output:

```
C:\Users\jayan\Desktop\c++.i + 
10
-----
Process exited after 0.6591 seconds with return value 0
Press any key to continue . . . |
```

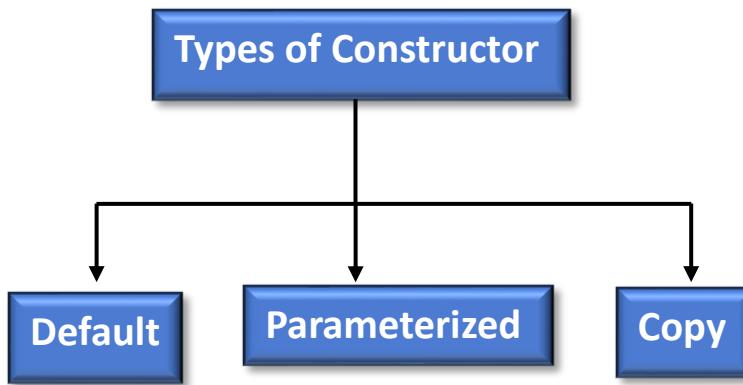

Constructor

- (i) Constructor in C++ is a special method that is invoked automatically at the time an object of a class is created.
- (ii) It is used to initialize the data members of new objects generally.
- (iii) The constructor in C++ has the same name as the class. It constructs the values i.e. provides data for the object which is why it is known as a constructor.

Syntax:

```
class className{  
    //access specifier  
    //Make Constructor  
  
    className(){  
        //Constructor Definition  
    }  
};  
  
//Main Function  
  
int main(){  
    //Create object  
    className obj;  
    return 0;  
}
```

Note: No need to call constructor through object because after creation of object, constructor will automatically executed.

Default Constructor:

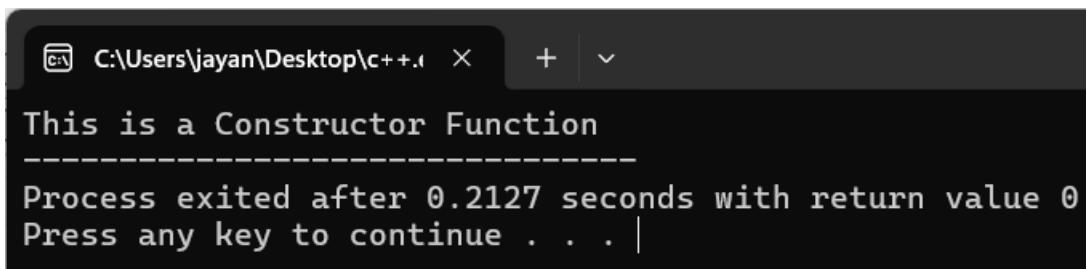

Default Constructor is the constructor which doesn't take any argument or parameter. It has no parameters. It's also called zero-parameter constructor.

Syntax:

```
class className{  
    //access specifier  
    //Make Constructor  
    className(){  
        //Constructor Definition  
    }  
};  
//Main Function  
int main(){  
    //Create object  
    className obj;  
    return 0;  
}
```

```
c++.cpp
1 #include<iostream>
2 using namespace std;
3 //Make class
4 class A {
5     public:
6         //Make Constructor
7         A(){
8             cout<<"This is a Constructor Function";
9         }
10    };
11 //Main Function
12 int main(){
13     //Object Creation or constructor calling
14     A obj;
15     return 0;
16 }
```

Output:

The screenshot shows a terminal window with the following text output:

```
C:\Users\jayan\Desktop\c++.i + 
This is a Constructor Function
-----
Process exited after 0.2127 seconds with return value 0
Press any key to continue . . . |
```

Parameterized Constructor:

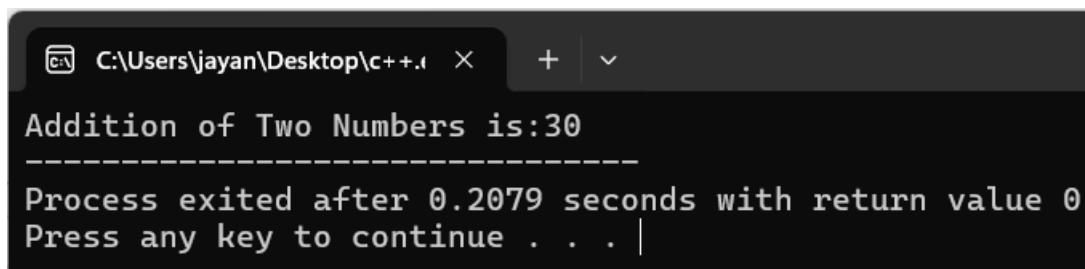

The constructor which take arguments or parameters is called parameterized constructor.

Syntax:

```
class className{  
    //access specifier  
    //Make Constructor  
    className(Number of Parameters){  
        //Constructor Definition  
    }  
};  
//Main Function  
int main(){  
    //Create object  
    className obj(Values of Parameters);  
    return 0;  
}
```

```
c++.cpp
1 #include<iostream>
2 using namespace std;
3 //Make class
4 class Add {
5     public:
6         //Make Constructor
7     Add(int num1,int num2){
8         int total=num1+num2;
9         cout<<"Addition of Two Numbers is:"<<total;
10    }
11 };
12 //Main Function
13 int main(){
14     //Object Creation or constructor calling
15     Add obj(20,10);
16     return 0;
17 }
```

Output:

```
C:\Users\jayan\Desktop\c++.i
Addition of Two Numbers is:30
-----
Process exited after 0.2079 seconds with return value 0
Press any key to continue . . . |
```

Copy Constructor:

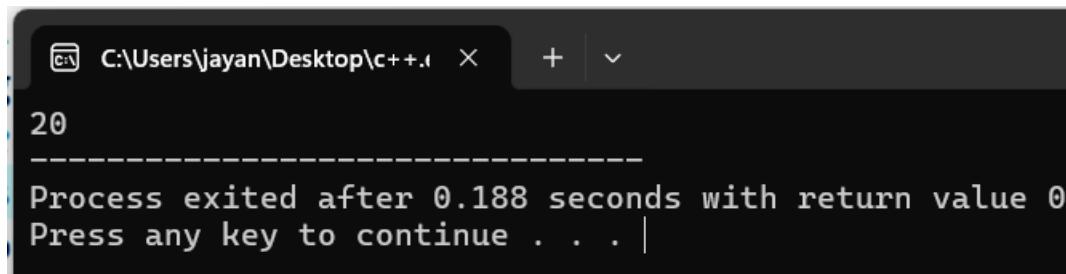

- (i) Copy Constructor is a type of constructor which is used to create a copy of an already existing object of a class type.
- (ii) A copy constructor is a member function that initializes an object using another object of the same class.
- (iii) The Compiler provides a default copy constructor to all the classes.

Syntax:

```
class className{  
//access specifier  
//Make Constructor  
    className(className &obj){  
        //Constructor Definition  
    }  
};
```

```
c++.cpp
1 #include<iostream>
2 using namespace std;
3 //Make class
4 class A {
5     public:
6         int x;
7         //Paramterized Constructor
8         A(int a){
9             x=a;
10        }
11        //Copy Constructor
12        A(A &i){
13            x=i.x;
14        }
15    };
16 //Main Function
17 int main(){
18     A a1(20); //Paramterized Constructor
19     A a2(a1); //Copy Constructor
20     cout<<a2.x;
21     return 0;
22 }
```

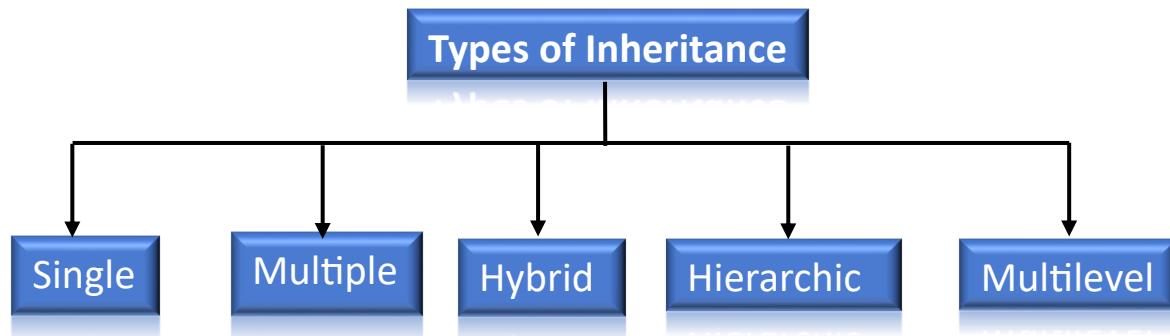

Output:

```
C:\Users\jayan\Desktop\c++.i + 
20
-----
Process exited after 0.188 seconds with return value 0
Press any key to continue . . . |
```

Inheritance

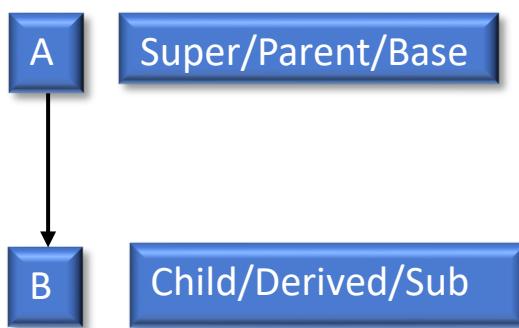

In C++, inheritance is a process in which one object acquires all the properties and behaviors of its parent object automatically. In such way, you can reuse, extend or modify the attributes and behaviors which are defined in other class.

Single Inheritance:

Single inheritance enables a derived class to inherit properties and behavior from a single parent class. It allows a derived class to inherit the properties or behavior of a base class, thus enabling code reusability as well as adding new features to the existing code.

Block Diagram:

Syntax:

Base Class:

```
class className{  
//Access Specifier  
//Data Members  
//Member Functions  
};
```

Derived Class:

```
class className : public BaseClassName{  
//Access Specifier  
//Function Definition of Base Class  
Or  
//Functions of Derived class  
};
```

Main Function

```
main(){  
derivedClassName objectName;  
objName.functionName();  
}
```

```

#include<iostream>
using namespace std;
//Parent Class
class Parent{
public:
    int num1,num2;
    int show();
};

//Child Class
class Child : public Parent{
public:
    int show(){
        cout<<"Enter First Number:";
        cin>>num1;
        cout<<"Enter Second Number:";
        cin>>num2;
        //print the numbers on screen
        cout<<"First Number is:"<<num1<<endl;
        cout<<"Second Number is:"<<num2;
    }
};

//Main Class
main(){
    Child obj;
    obj.show();
}

23 main(){
24     Child obj;
25     obj.show();
26 }
27

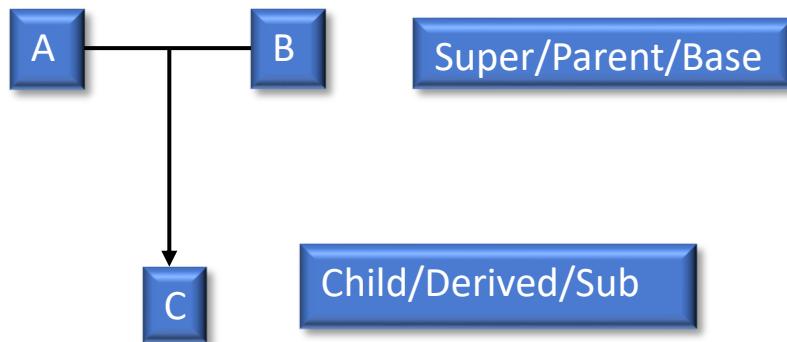

```

Output:

```
C:\Users\jayan\Desktop\c++.i + ▾
Enter First Number:20
Enter Second Number:20
First Number is:20
Second Number is:20
-----
Process exited after 3.995 seconds with return value 0
Press any key to continue . . . |
```

Multiple Inheritance:

Multiple Inheritance is a type of inheritance where a class can inherit from more than one classes.

```

#include<iostream>
using namespace std;
//Parent Class 1
class Father{
    public:
        int num1,num2;
        int show();
};

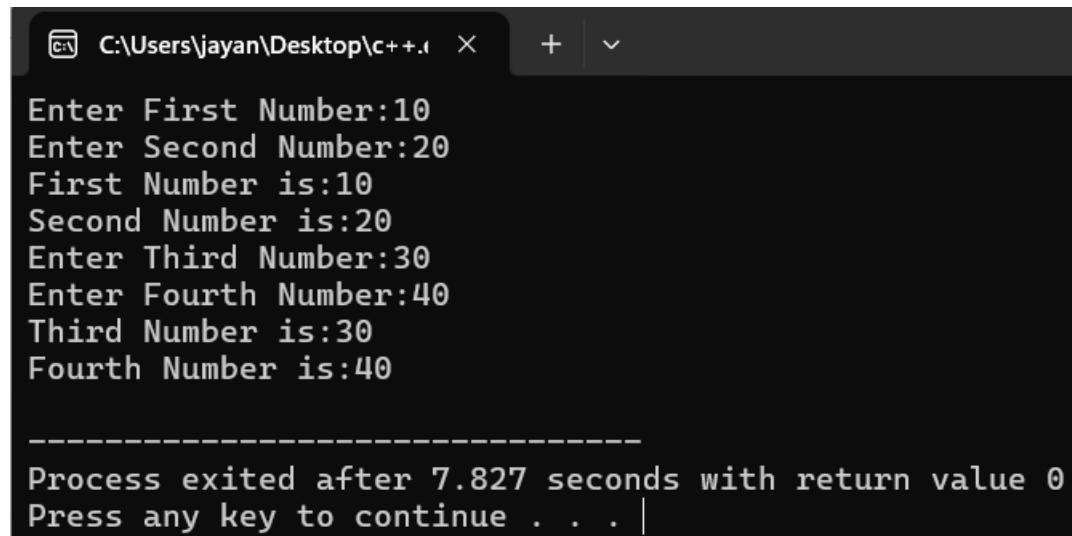

//Parent Class 2
class Mother{
    public:
        int num3,num4;
        int get_show();
};

//Child Class
class Child : public Father,public Mother{
    public:
        int show(){
            cout<<"Enter First Number:";
            cin>>num1;
            cout<<"Enter Second Number:";
            cin>>num2;
            //print the numbers on screen
            cout<<"First Number is:"<<num1<<endl;
            cout<<"Second Number is:"<<num2<<endl;
}

```

```
23     //print the numbers on screen
24     cout<<"First Number is:"<<num1<<endl;
25     cout<<"Second Number is:"<<num2<<endl;
26     return 0;
27 }
28 int get_show(){
29     cout<<"Enter Third Number:";
30     cin>>num3;
31     cout<<"Enter Fourth Number:";
32     cin>>num4;
33     //print the numbers on screen
34     cout<<"Third Number is:"<<num3<<endl;
35     cout<<"Fourth Number is:"<<num4<<endl;
36     return 0;
37 }
38 }
39 //Main Class
40 main(){
41     Child obj;
42     obj.show();
43     obj.get_show();
44 }
45
```

Output:

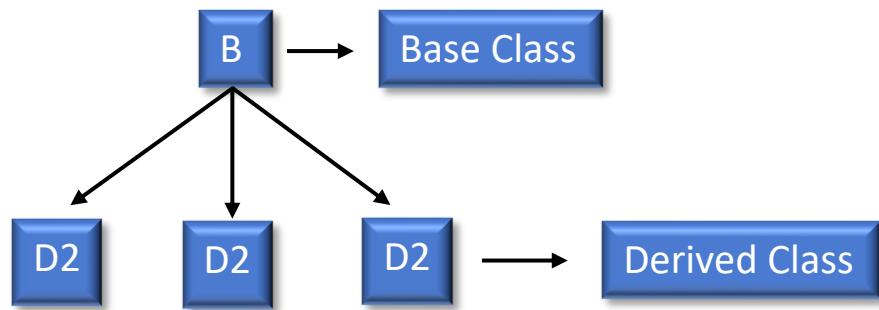

```
C:\Users\jayan\Desktop\c++.i + ▾
Enter First Number:10
Enter Second Number:20
First Number is:10
Second Number is:20
Enter Third Number:30
Enter Fourth Number:40
Third Number is:30
Fourth Number is:40

-----
Process exited after 7.827 seconds with return value 0
Press any key to continue . . . |
```

Hierarchical Inheritance

Hierarchical inheritance is a kind of inheritance where more than one class is inherited from a single parent class.

```
#include<iostream>
using namespace std;
//Base Class
class Base{
public:
    int add(int num1,int num2);
    int sub(int num3,int num4);
};

//Derived Class 1
class Derived1 : public Base{
public:
    int add(int num1,int num2){
        int total1=num1+num2;
        cout<<"Addition of Two Numbers is:"<<total1<<endl;
        return 0;
    }
};

//Derived Class 2
class Derived2 : public Base{
public:
    int sub(int num3,int num4){
        int total2=num3-num4;
        cout<<"Subtraction of Two Numbers is:"<<total2<<endl;
        return 0;
    }
};
```

```

        int sub(int num3,int num4){
            int total2=num3-num4;
            cout<<"Subtraction of Two Numbers is:"<<total2<<endl;
            return 0;
        }
    //Main Function
int main(){
    //Create Object
    Derived1 obj1;
    Derived2 obj2;
    //Call the functions through objects
    obj1.add(10,20);
    obj2.sub(20,10);
    return 0;
}

```

Output:

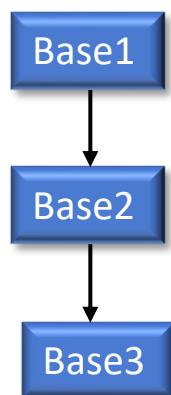

```

C:\Users\jayan\Desktop\c++.i X + | v
Addition of Two Numbers is:30
Subtraction of Two Numbers is:10
-----
Process exited after 0.4532 seconds with return value 0
Press any key to continue . . .

```

Multilevel Inheritance:

In this inheritance, user can make different classes as (parent) without create Derived classes.

```

c++.cpp
1 #include<iostream>
2 using namespace std;
3 //Base Class 1
4 class Base1{
5     public:
6         int num1=10;
7     };
8 //Base Class 2
9 class Base2{
10    public:
11        int num2=20;
12    };
13 //Base Class 3
14 class Base3{
15    public:
16        int num3=30;
17    };
18 //Main Function
19 int main(){
20     Base1 obj1;
21     Base2 obj2;
22     Base3 obj3;
23     cout<<"Number of Base Class 1 is:"<<obj1.num1<<endl;
24     cout<<"Number of Base Class 2 is:"<<obj2.num2<<endl;
25     cout<<"Number of Base Class 3 is:"<<obj3.num3<<endl;
26
27     return 0;
28 }

```

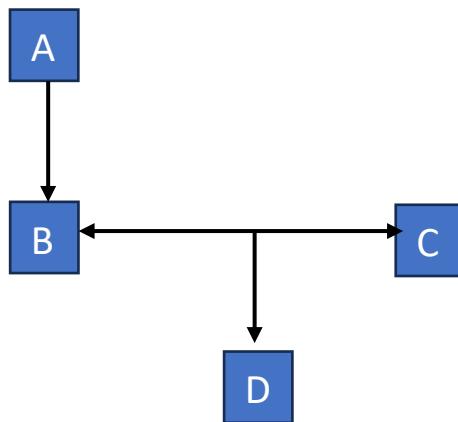

Line	Col	File	Message
6	11	C:\Users\jayan\Desktop\c++.cpp	[Warning] non-static data member initializers only available with -std=c++11 or -std=gnu++11
11	11	C:\Users\jayan\Desktop\c++.cpp	[Warning] non-static data member initializers only available with -std=c++11 or -std=gnu++11
16	11	C:\Users\jayan\Desktop\c++.cpp	[Warning] non-static data member initializers only available with -std=c++11 or -std=gnu++11

Output:

```
C:\Users\jayan\Desktop\c++.i + 
Number of Base Class 1 is:10
Number of Base Class 2 is:20
Number of Base Class 3 is:30
-----
Process exited after 0.6266 seconds with return value 0
Press any key to continue . . . |
```

Hybrid Inheritance:

In Hybrid Inheritance, multiple types of inheritance are combined within a single class hierarchy, enabling a varied and flexible structure of classes. In hybrid inheritance, within the same class, we can have elements of single inheritance, multiple inheritance, multilevel inheritance, and hierarchical inheritance

```
#include<iostream>
using namespace std;
//Base Class 1
class Base{
public:
    int base1();
};

//Child Class 1 or Base 2 class
class Child1 : public Base{
public:
    int num1=10;
    int base1(){
        cout<<"This is First Base Class" << endl
    }
};

//Base 3 class
class Base3{
public:
    int num2=20;
};

//Child class 2
class Child2 : public Child1,public Base3{
public:
    void showData(){
        cout<<"First Number is:" << num1 << endl;
    }
};
```

```

21 //Child class 2
22 class Child2 : public Child1,public Base3{
23     public:
24     void showData(){
25         cout<<"First Number is:"<<num1<<endl;
26         cout<<"Second Number is:"<<num2<<endl;
27     }
28 };
29 //Main class
30 main(){
31     Child1 obj;
32     Child2 obj2;
33     obj.base1();
34     obj2.showData();
35 }

```

Line	Col	File	Message
11	12	C:\Users\jayan\Desktop\c++.cpp	[Warning] non-static data member initializers only available with -std=c++11 or -std=gnu++11
19	12	C:\Users\jayan\Desktop\c++.cpp	[Warning] non-static data member initializers only available with -std=c++11 or -std=gnu++11

Output:

```

C:\Users\jayan\Desktop\c++.i  X + 
This is First Base Class
First Number is:10
Second Number is:20

-----
Process exited after 0.5858 seconds with return value 0
Press any key to continue . . .

```

Scope resolution operator

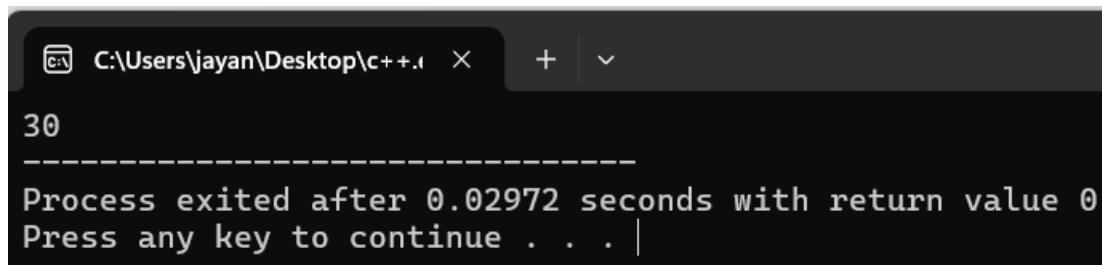

The scope resolution operator is used to reference the global variable or member function that is out of scope. Therefore, we use the scope resolution operator to access the hidden variable or function of a program. The operator is represented as the double colon (::) symbol.

Uses of Scope Resolution Operator

- (i)It is used to access the hidden variables or member functions of a program.
- (ii)It defines the member function outside of the class using the scope resolution.
- (iii)It is used to access the static variable and static function of a class.
- (iv)The scope resolution operator is used to override function in the Inheritance.

```
#include<iostream>
using namespace std;
class Scope_Resolution{
public:
    int add(int num1,int num2);
}
int Scope_Resolution::add(int num1,int num2){
    int total=num1+num2;
    cout<<total;
}
main(){
    Scope_Resolution obj;
    obj.add(20,10);
}
```

Output:

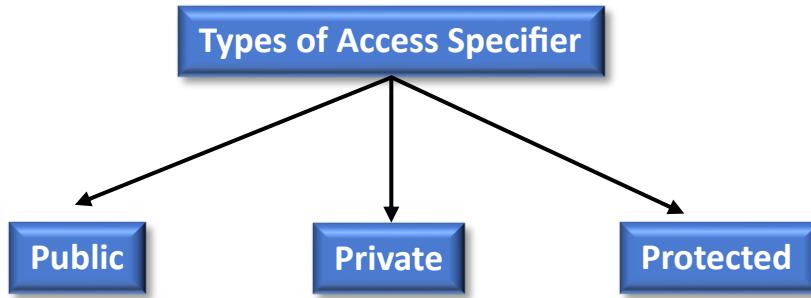

A screenshot of a terminal window titled "C:\Users\jayan\Desktop\c++.i". The window displays the following text:
30

Process exited after 0.02972 seconds with return value 0
Press any key to continue . . . |

Access Specifiers

- (i) Access Specifier is used for data hiding and it's also known as Access Modifier.
- (ii) Data hiding refers to restricting access to data members of a class. This is to prevent other functions and classes from tampering with the class data.
- (iii) However, it is also important to make some member functions and member data accessible so that the hidden data can be manipulated indirectly.
- (iv) The access modifiers of C++ allow us to determine which class members are accessible to other classes and functions, and which are not.
- (v) By default private access specifier will be executed in class.

Public:

- (i)The public keyword is used to create public members (data and functions).
- (ii)The public members are accessible from any part of the program.

```
c++.cpp
1 #include<iostream>
2 using namespace std;
3 //Class
4 class A{
5     public:
6         int a=10;
7     };
8 //Main function;
9 main(){
10    A obj;
11    cout<<"Value is:"<<obj.a;
12 }
```

Output:

```
C:\Users\jayan\Desktop\c++.i
Value is:10
-----
Process exited after 0.6456 seconds with return value 0
Press any key to continue . . . |
```

Private:

- (i)The private keyword is used to create private members (data and functions).
- (ii)The private members can only be accessed from within the class.
- (iii)However, friend classes and friend functions can access private members.

The screenshot shows a code editor window with a tab labeled "c++.cpp". The code is as follows:

```
1 //include
2 using namespace std;
3 //Class
4 class A{
5     private:
6         int a=10;
7     public:
8         void value(){
9             cout<<"Value of A is:"<<a;
10            }
11
12 };
13 //Main function;
14 main(){
15     A obj;
16     obj.value();
17 }
```

The line "obj.value();" is highlighted in light blue.

Output:

The screenshot shows a terminal window with the following output:

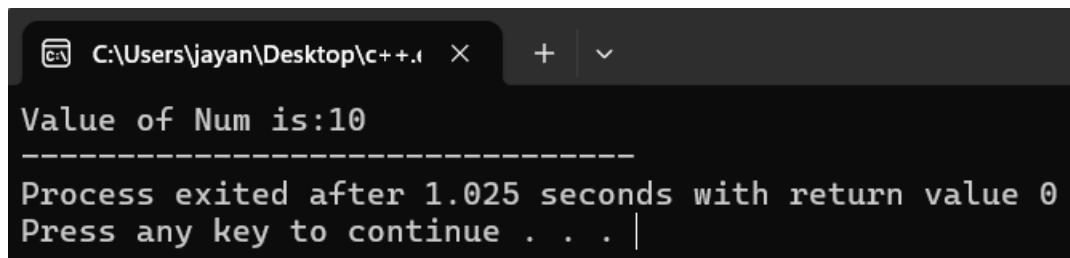

```
C:\Users\jayan\Desktop\c++.i
Value of A is:10
-----
Process exited after 0.5246 seconds with return value 0
Press any key to continue . . . |
```

Protected:

- (i)The protected keyword is used to create protected members (data and function).
- (ii)The protected members can be accessed within the class and from the derived class.

```
[*] c++.cpp
1 #include<iostream>
2 using namespace std;
3 //Class
4 class A{
5     protected:
6         int num=10;
7 };
8 class B : protected A{
9     public:
10    void showData(){
11        cout<<"Value of Num is:"<<num;
12    }
13 };
14 //Main function;
15 main(){
16     B obj;
17     obj.showData();
18 }
```

Output:

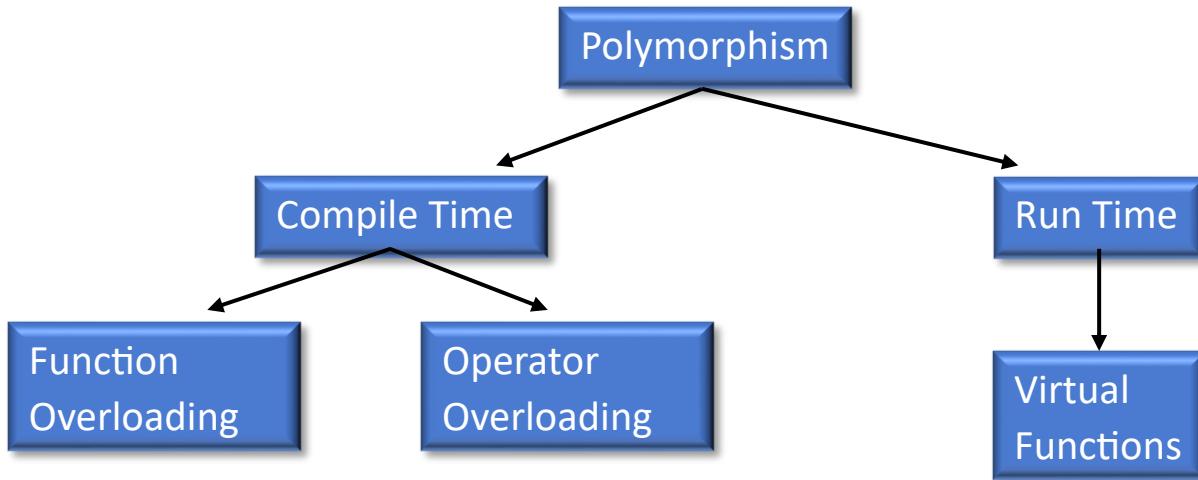

A screenshot of a terminal window titled "C:\Users\jayan\Desktop\c++.1". The window contains the following text:
Value of Num is:10

Process exited after 1.025 seconds with return value 0
Press any key to continue . . . |

Polymorphism

(i) Poly means many or morphism means forms.

(ii) Polymorphism refers to the ability to call different functions by using only one type of function call.

Function Overloading:

(i) When there are multiple functions with the same name but different parameters, then the functions are said to be overloaded, hence this is known as Function Overloading.

(ii) Functions can be overloaded by changing the number of arguments or changing the type of arguments.

(iii) In simple terms, it is a feature of object-oriented programming providing many functions that have the same name but distinct parameters when numerous tasks are listed under one function name.

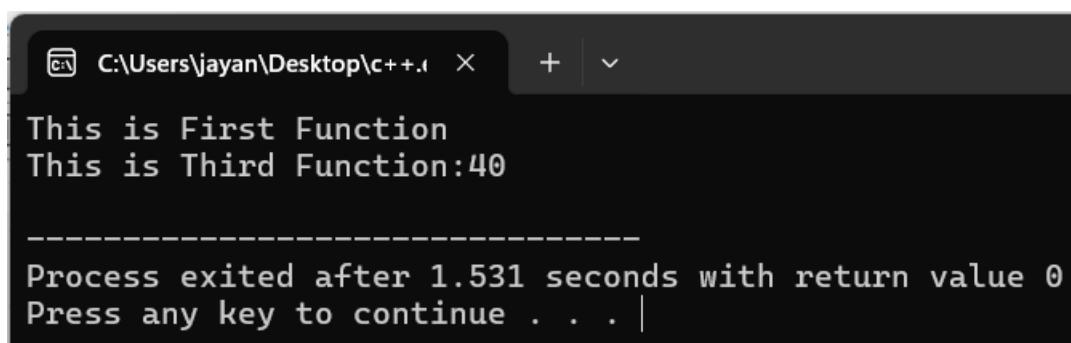

Rules of Function Overloading:

(i) Function name must be same.

(ii) Number of parameters or data types of parameters can be changeable.

```
c++.cpp
1 #include<iostream>
2 using namespace std;
3 //Create Functions
4 void fun(){
5     cout<<"This is First Function" << endl;
6 }
7
8 void fun(int a){
9     cout<<"This is Second Function:" << a << endl;
10}
11
12 void fun(int a,int b){
13     cout<<"This is Third Function:" << a+b << endl;
14}
15 //Main Function
16 main(){
17     fun();
18     fun(30,10);
19 }
```

Output:

```
C:\Users\jayan\Desktop\c++.i
This is First Function
This is Third Function:40
-----
Process exited after 1.531 seconds with return value 0
Press any key to continue . . . |
```

Operator Overloading:

C++ has the ability to provide the operators with a special meaning for a data type, this ability is known as operator overloading. Operator overloading is a compile-time polymorphism.

For example: we can overload an operator ‘+’ in a class like String so that we can concatenate two strings by just using +. Other example classes where arithmetic operators may be overloaded are Complex Numbers, Fractional Numbers, Big integers, etc.

Rules for operator overloading:

- (i) Existing operators can only be overloaded, but the new operators cannot be overloaded.
- (ii) The overloaded operator contains at least one operand of the user-defined data type.
- (iii) We cannot use friend function to overload certain operators. However, the member function can be used to overload those operators.
- (iv) When unary operators are overloaded through a member function take no explicit arguments, but, if they are overloaded by a friend function, takes one argument.
- (iv) When binary operators are overloaded through a member function takes one explicit argument, and if they are overloaded through a friend function takes two explicit arguments.

```
[*] c++.cpp
1 #include <iostream>
2 using namespace std;
3 class A
4 {
5     int x;
6     public:
7     A(){}
8     A(int i)
9     {
10         x=i;
11     }
12     void operator+(A);
13     void display();
14 };
15 void A :: operator+(A a)
16 {
17     int m = x+a.x;
18     cout<<"The result of the addition of two objects is : "<<m;
19 }
20 int main()
21 {
22     A a1(5);
23     A a2(4);
24     a1+a2;
25 }
```

Output:

```
C:\Users\jayan\Desktop\c++.i  X  +  ▾
The result of the addition of two objects is : 9
-----
Process exited after 0.8991 seconds with return value 0
Press any key to continue . . . |
```

Virtual Functions:

- (i) Virtual functions are public member functions, used for special purpose. These are defined in base class and again are re-defined in the derived class.
- (ii) They are mainly used to achieve runtime polymorphism.
- (iii) Virtual functions are declared with a virtual keyword in a base class.

Rules of virtual functions:

- (i) Virtual functions cannot be static.
- (ii) A virtual function can be a friend function of another class.
- (iii) Virtual functions should be accessed using a pointer or reference of base class type to achieve runtime polymorphism.
- (iv) A class may have a virtual destructor but it cannot have a virtual constructor.

```
c++.cpp
1 #include<iostream>
2 using namespace std;
3
4 class Base{
5     public:
6         virtual void print(){
7             cout<<"This is base class function" << endl;
8         }
9     };
10 class Derived : public Base{
11     public:
12         void print(){
13             cout<<"This is Derived class function" << endl;
14         }
15     };
16 //Main class
17 int main(){
18     Base* print;
19     Derived obj;
20     print=&obj;
21     print->print(); //function call
22     return 0;
23 }
```

Output:

```
C:\Users\jayan\Desktop\c++.i  X  +  ▾
This is Derived class function
-----
Process exited after 0.2013 seconds with return value 0
Press any key to continue . . . |
```

This pointer

Every object in C++ has access to its own address through an important pointer called this pointer. The (this) pointer is an implicit parameter to all member functions. Therefore, inside a member function, this may be used to refer to the invoking object.

Friend functions do not have a (this) pointer, because friends are not members of a class. Only member functions have a (this) pointer.

```
c++.cpp
1 #include <iostream>
2 using namespace std;
3 class Employee {
4     public:
5         int id; //data member (also instance variable)
6         string name; //data member(also instance variable)
7         float salary;
8         Employee(int id, string name, float salary)
9         {
10             | this->id = id;
11             | this->name = name;
12             | this->salary = salary;
13         }
14         void display()
15         {
16             cout<<id<<"  "<<name<<"  "<<salary<<endl;
17         }
18     };
19 int main(void) {
20     Employee e1 =Employee(101, "Sonoo", 890000); //creating an object of Employee
21     Employee e2=Employee(102, "Nakul", 59000); //creating an object of Employee
22     e1.display();
23     e2.display();
24     return 0;
25 }
```

Output:

```
C:\Users\jayan\Desktop\c++.i + | v
101 Sonoo 890000
102 Nakul 59000
-----
Process exited after 0.8571 seconds with return value 0
Press any key to continue . . . |
```

New and Delete Operator

(i) In C++ programming language, the new and delete operators are mainly utilized for dynamic memory allocation and deallocation. They enable us to dynamically allocate and free the memory, which means that we can create objects whose size and lifetime may be defined at runtime. However, there are some main distinctions between the two operators that we should be aware of.

(ii) The new operator is mainly utilized to allocate memory for an object or an array of objects. It returns a pointer to the allocated memory. On the other hand, the delete operator is mainly utilized to deallocate memory that was previously allocated with new. It frees the memory pointed to by the pointer and sets the pointer to null.

Syntax (New Operator)

```
pointer_variable = new data_type;
```

Syntax (Delete Operator)

```
delete pointer_variable;
```

Initialization

The new operator initializes the memory allocated for an object with the default constructor of the class. If there is no default constructor, we may utilize the placement new operator to call the appropriate constructor. The delete operator does not perform any initialization.

Allocation

The new operator may be mainly utilized to allocate memory for an array of objects. The syntax for array allocation is:

1.

```
pointer_variable = new data_type[array_size];
```

On the other hand, the delete operator may be mainly utilized to deallocate an array of objects allocated with the new operator. The syntax for array deallocation is:

```
delete[] pointer_variable;
```

New Operator

```
c++.cpp
1 #include <iostream>
2 using namespace std;
3 int main () {
4     int *ptr1 = NULL;
5     ptr1 = new int;
6     float *ptr2 = new float(223.324);
7     int *ptr3 = new int[28];
8     *ptr1 = 28;
9     cout << "Value of pointer variable 1 : " << *ptr1 << endl;
10    cout << "Value of pointer variable 2 : " << *ptr2 << endl;
11    if (!ptr3)
12        cout << "Allocation of memory failed\n";
13    else {
14        for (int i = 10; i < 15; i++)
15            ptr3[i] = i+1;
16        cout << "Value of store in block of memory: ";
17        for (int i = 10; i < 15; i++)
18            cout << ptr3[i] << " ";
19    }
20    return 0;
21 }
```

Output:

```
C:\Users\jayan\Desktop\c++.i  X  +  v
Value of pointer variable 1 : 28
Value of pointer variable 2 : 223.324
Value of store in block of memory: 11 12 13 14 15
-----
Process exited after 0.6354 seconds with return value 0
Press any key to continue . . . |
```

Delete Operator:

```
c++.cpp
1 #include <iostream>
2 using namespace std;
3 int main () {
4     int *ptr1 = NULL;
5     ptr1 = new int;
6     float *ptr2 = new float(299.121);
7     int *ptr3 = new int[28];
8     *ptr1 = 28;
9     cout << "Value of pointer variable 1 : " << *ptr1 << endl;
10    cout << "Value of pointer variable 2 : " << *ptr2 << endl;
11    if (!ptr3)
12        cout << "Allocation of memory failed\n";
13    else {
14        for (int i = 10; i < 15; i++)
15            ptr3[i] = i+1;
16        cout << "Value of store in block of memory: ";
17        for (int i = 10; i < 15; i++)
18            cout << ptr3[i] << " ";
19    }
20    delete ptr1;
21    delete ptr2;
22    delete[] ptr3;
23    return 0;
24 }
```

Output:

```
C:\Users\jayan\Desktop\c++.i  X  +  ▾
Value of pointer variable 1 : 28
Value of pointer variable 2 : 299.121
Value of store in block of memory: 11 12 13 14 15
-----
Process exited after 1.476 seconds with return value 0
Press any key to continue . . . |
```

Files Handling

- (i) File handling is used to store data permanently in a computer. Using file handling we can store our data in secondary memory (Hard disk).
- (ii) In C++ programming we are using the iostream standard library, it provides cin and cout methods for reading from input and writing to output respectively.
- (iii) To read and write from a file we are using the standard C++ library called fstream
- (iv) File handling in C++ is a mechanism to create and perform read/write operations on a file.

Operations of File Handling(fstream):

Sr.No	Data Type & Description
1	ofstream This data type represents the output file stream and is used to create files and to write information to files.
2	ifstream This data type represents the input file stream and is used to read information from files.
3	fstream This data type represents the file stream generally, and has the capabilities of both ofstream and ifstream which means it can create files, write information to files, and read information from files.

Steps of File Handling:

- Step1: Naming a file
- Step2: Opening a file
- Step3: Writing data into the file
- Step4: Reading data from the file
- Step5: Closing a file.

Flags:

ios::in	Open a file for reading.
ios::out	Open a file for writing.
ios::binary	Open a file in binary instead of text.
ios::ate	File pointer points at the end of file after opening.
ios::app	Appends the new content at the end of file
ios::trunc	If files exists, all of its content is discarded.

Functions of File Handling:

No.	Function	Description
1	fopen()	opens new or existing file
2	fprintf()	write data into the file
3	fscanf()	reads data from the file
4	fputc()	writes a character into the file
5	fgetc()	reads a character from file
6	fclose()	closes the file
7	fseek()	sets the file pointer to given position

Modes of File Handling

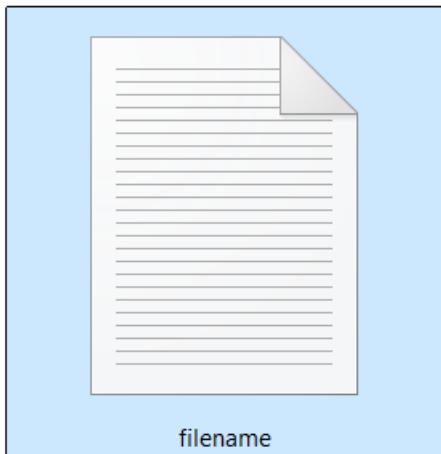

Mode	Description
r	opens a text file in read mode
w	opens a text file in write mode
a	opens a text file in append mode
r+	opens a text file in read and write mode

w+	opens a text file in read and write mode
a+	opens a text file in read and write mode
rb	opens a binary file in read mode
wb	opens a binary file in write mode
ab	opens a binary file in append mode
rb+	opens a binary file in read and write mode
wb+	opens a binary file in read and write mode
ab+	opens a binary file in read and write mode

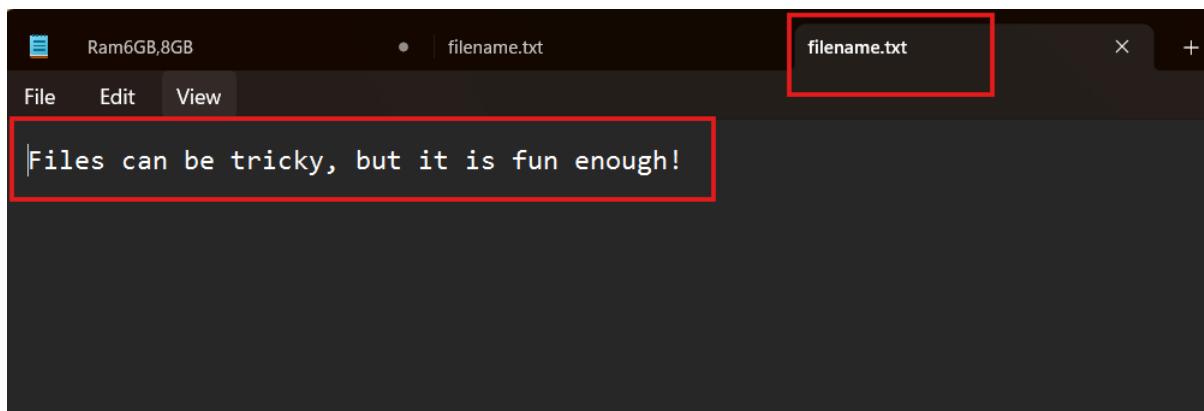

Create and Write a file

```
c++.cpp
1 #include <iostream>
2 #include <fstream>
3 using namespace std;
4 int main() {
5     // Create and open a text file
6     ofstream MyFile("C:/Users/jayan/Desktop/filename.txt");
7
8     // Write to the file
9     MyFile << "Files can be tricky, but it is fun enough!";
10
11    // Close the file
12    MyFile.close();
13 }
```

Output:

Note: Go to your file location where you saved, then open this file for show content.

Reading Content from file

```
c++-cpp
1 #include <iostream>
2 #include <fstream>
3 #include <string>
4 using namespace std;
5 int main () {
6     // Create a text file
7     ofstream MyWriteFile("C:/Users/jayan/Desktop/filename.txt");
8     // Write to the file
9     MyWriteFile << "Files can be tricky, but it is fun enough!";
10    // Close the file
11    MyWriteFile.close();
12    // Create a text string, which is used to output the text file
13    string myText;
14    // Read from the text file
15    ifstream MyReadFile("filename.txt");
16    // Use a while Loop together with the getline() function to read the file Line by Line
17    while (getline (MyReadFile, myText)) {
18        // Output the text from the file
19        cout << myText;
20    }
21    // Close the file
22    MyReadFile.close();
23 }
```

Output:

```
Files can be tricky, but it is fun enough!
-----
Process exited after 1.012 seconds with return value 0
Press any key to continue . . . |
```

Exception Handling

(i) An exception is a problem that arises during the execution of a program. A C++ exception is a response to an exceptional circumstance that arises while a program is running, such as an attempt to divide by zero.

(ii) Exceptions provide a way to transfer control from one part of a program to another. C++ exception handling is built upon three keywords: try, catch, and throw.

Try	A try block identifies a block of code for which particular exceptions will be activated. It's followed by one or more catch blocks.
Catch	A program catches an exception with an exception handler at the place in a program where you want to handle the problem. The catch keyword indicates the catching of an exception.
Throw	A program throws an exception when a problem shows up. This is done using a throw keyword.

Syntax:

```
try {  
    // protected code  
} catch( ExceptionName e1 ) {  
    // catch block  
} catch( ExceptionName e2 ) {  
    // catch block  
} catch( ExceptionName eN ) {  
    // catch block  
}
```

```
c++.cpp
1 #include <iostream>
2 using namespace std;
3 //Main Function
4 int main() {
5     try {
6         int age = 15;
7         if (age >= 18) {
8             cout << "Access granted - you are old enough.";
9         } else {
10            throw 505;
11        }
12    }
13    catch (int myNum) {
14        cout << "Access denied - You must be at least 18 years old.\n";
15        cout << "Error number: " << myNum;
16    }
17    return 0;
18 }
19
```

Output

```
C:\Users\jayan\Desktop\c++.i × + ▾
Access denied - You must be at least 18 years old.
Error number: 505
-----
Process exited after 0.4669 seconds with return value 0
Press any key to continue . . . |
```

Friend Function

A friend class can access private and protected members of other classes in which it is declared as a friend. It is sometimes useful to allow a particular class to access private and protected members of other classes.

Syntax:

```
class class_name  
{  
    friend data_type function_name(argument/s);  
}
```

Characteristics of Friend Function:

- (i)The function is not in the scope of the class to which it has been declared as a friend.
- (ii)It cannot be called using the object as it is not in the scope of that class.
- (iii)It can be invoked like a normal function without using the object.
- (iv)It cannot access the member names directly and has to use an object name and dot membership operator with the member name.
- (v)It can be declared either in the private or the public part.

```
[*] c++.cpp
1 #include <iostream>
2 using namespace std;
3 class Distance {
4     private:
5         int meter;
6         // friend function
7         friend int addFive(Distance);
8     public:
9         Distance() : meter(0) {}
10
11    };
12 // friend function definition
13 int addFive(Distance d) {
14     //accessing private members from the friend function
15     d.meter += 5;
16     return d.meter;
17 }
18 int main() {
19     Distance D;
20     cout << "Distance: " << addFive(D);
21     return 0;
22 }
```

Output:

```
C:\Users\jayan\Desktop\c++.i X + | v
Distance: 5
-----
Process exited after 0.5577 seconds with return value 0
Press any key to continue . . . |
```
